Treatment of the Toxemias of Pregnancy

by

B. P. WATSON, M.D.,

New York, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

WHEN the term "pregnancy toxemia" first was used in obstetric literature it was thought to be a definite entity caused by the presence of some specific toxin or toxins found only in the pregnant state. The search for these specific toxins so far has been unsuccessful and most of us now believe that many of the clinical types grouped under the general term "pregnancy toxemia" are not peculiar to pregnancy at all but are expressions of pathologic states brought to light for the first time, or aggravated, in the course of pregnancy.

One of the early exponents of this view was Dr. W. W. Herrick, who as consulting physician to the Sloane Hospital for Women for the past ten years has taken a special interest in those cases. In his work in our clinic he has the assistance of Dr. Jean Corwin and of Dr. Alvin J. B. Tillman. Special prenatal clinics under their direction have been organized for the observation and treatment of toxemia cases, and in the Hospital a special ward is set apart for those cases which require hospitalization. A follow-up clinic also is conducted and a special effort is being made to keep in touch with all cases over a period of years, in order to learn something more definite than is known at present of the ultimate outcome of these episodes in pregnancy and of their effects on future health and longevity. In all this work there is the closest possible cooperation between internist and obstetrician so that when it comes to making a decision with regard to treatment the patient gets the benefit of the experience of both. What I have to say today is the outcome of this combined experience, with grateful acknowledgment of the contribution made by our medical colleagues.

The subject of this communication is treatment as at present carried out in the Sloane Hospital for Women and a consideration of the results obtained.

Treatment of Early Pregnancy Toxemia

We have discarded the old classification into three groups of neurotic, reflex, and toxic, and as a working basis for treatment regard them

all as of the toxic variety, at the same time admitting that there still is considerable doubt as to the nature of the toxic process involved and recognizing that many of the patients are of the nervous, imaginative type.

It seems logical to suppose that the same process is concerned in the mild as in the severe cases. In the latter there always is a history of some days or weeks of mild nausea or emesis which usually has gone on untreated. In our hands the most effective treatment for those early cases is the instruction of the patients regarding the frequency of eating and the necessity for an increase in carbohydrates and sugar in the diet. They are told to eat at least seven times a day—a cracker or some fruit first thing on waking and and before getting out of bed; breakfast; crackers or some fruit at 11:00 a.m.; lunch; afternoon tea with crackers or bread and jam at 4:00 p. m.; supper; and then always something before going to bed at night. We have found that these patients who have the most marked nausea in the evening, just before or during the evening meal, have had a five or six hour fast between that meal and lunch. A small meal at 4 o'clock usually will allow them full enjoyment of dinner. They are instructed to eat freely of carbohydrates in the form of bread stuffs and cereals; of sugar, as such and in the form of candy, jams and jellies, and of fresh fruits and green vegetables. A minimum of fat in the form of cream and of meat, a small amount only, are prescribed once a day.

If such a regime is instituted at the beginning of even slight nausea the trying period of the first three months can be got through comfortably. We instruct our private patients in this way at the first visit, even if they have no nausea, so that at its earliest appearance they may begin the regime. We are convinced that if treatment were begun thus early in all cases we would have fewer cases of the severe type of vomiting. The theory on which this treatment is based is that in early pregnancy the rapid growth of the ovum causes a deprivation of glycogen from the mother. The theory may be wrong, but the effects of the treatment are satisfactory in the great majority of cases.

The same line of treatment is followed with modification in the more severe cases where there is continuous nausea and frequent emesis. Such patients should be put to bed and kept quiet. Hospitalization is not always necessary but is advisable in many instances, as there is often a nervous element present. Quiet, freedom from household cares, and from visits of relatives and friends are important factors in the treatment of these individuals. For twenty-four hours all nourishment and fluids by mouth are withheld, and normal saline is given by rectum in quantities of six ounces every four hours. A colonic irrigation precedes the treatment and is repeated daily. If the patients are not dehydrated at the end of this twenty-four hours, two-hourly feeding is begun—ginger ale, thin toast with jelly, tea with sugar, cooked cereal, custard, stewed fruit, baked potato—all in small amounts at a time. If the patients do well on this the number of feedings is gradually reduced and the quantities increased, so that after some days they are eating only from five to seven times a day. It always is wise to find out the sort of food the patient likes and to let her have that if it conforms to the general scheme.

If dehydration is present at the end of the first twenty-four hours, or prior to it, 500 c.c. of 10 per cent glucose in normal saline are given intravenously every twelve hours, or every eight hours in severe cases. Nothing is given by mouth while they are getting the injections. The rectal saline is continued as in severe cases. The great majority show improvement after forty-eight hours of this treatment and mouth feeding is gradually resumed.

Sedatives of some kind are required by most patients. Phenobarbitol, 1 to 3 grains every four hours by hypodermic, or sodium bromide, grs. XXX and chloral grs. XV in the four-hourly rectal tap are given. In very nervous patients both forms of medication may be necessary. After feeding has begun the phenobarbitol in diminishing quantities is continued.

The mouth is apt to get dry, the tongue to crack, and a general stomatitis to develop. It is important that the mouth be kept as clean as possible. Dobell's solution or aluminum acetate, 2 per cent, are used as mouth washes. The lips are washed with lemon juice and glycerine, equal parts. If there is bleeding from the gums or lips the bleeding areas may be cauterized with silver nitrate (5 to 10 per cent).

If in spite of all treatment mentioned vomiting still continues, gastric lavage may be employed in addition, or the duodenal tube is passed and 10 per cent glucose, 10 per cent Karo syrup, and raw eggs are fed through it. In some patients the employment of gastric lavage or the duodenal bucket seems to work like a charm in stopping the vomiting. Al-

ways an intake of 3000 to 4000 c.c. of fluid per day is aimed at.

If after the employment of all these methods or at any time in the course of the illness the patient is steadily going down hill the question of terminating the pregnancy comes up. The decision for or against this is one of our most difficult clinical problems. The conditions demanding termination include tachycardia, jaundice, diminished output of urine, bleeding from the gums and nose together with ecchymotic areas round hypodermic injections, increasing nitrogen retention, mental apathy and disorientation, associated renal disease, such as pyelitis and prolonged low fever. The decision must be made on a general consideration of all these factors. Stander has reported two cases which showed marked retinal hemorrhages, one of whom died. We have had two patients both of which died, one in spite of therapeutic abortion and one during the course of her pregnancy. In these two patients there were renal lesions present. One had a cortical necrosis of the kidneys and the other a pyelonephritis. In all cases the eyes should be carefully examined.

Treatment of Late Pregnancy Toxemia

We already have stated that several distinct clinical entities are included in the term late pregnancy toxemia. Some of the symptoms and signs are common to all of them so that on their first detection it is usually impossible to assign the case to a definite clinical group. The conditions indicating the necessity for treatment may be systolic blood pressure above 130 mm. of mercury, albuminuria, edema of face and hands, headache, visual disturbances, vomiting, epigastric pain. Patients presenting any one, or any combination of, these symptoms require careful observation in bed either at home or in a hospital. During the period of investigation it is necessary to have a general form of treatment likely to be of benefit, or at least not harmful.

In the Sloane Hospital that routine for the ordinary case is a very simple one consisting of rest in bed and the administration of a salt poor diet, together with attention to the movement of the bowels. We formerly gave a low protein diet but now the diet is the ordinary one with low salt intake. This diet gives, approximately, 2,200 calories and contains 1.75 gms. of salt and 75 gms. of protein. All salt, as such, is excluded. All the food is prepared without the addition of salt. Salt poor bread is used. Two-and-one-half cups of milk are allowed which is about half of what the ordinary patient gets. High caloric extras, such as egg nogs and chocolate malted milk, grape juice, etc., are added when required. The following are typical menus for the day:

Breakfast: Orange; Farina with 10% cream and sugar; Egg; Toast, one slice with butter; Coffee with 10% cream and sugar.

10:00 A. M.: One glass of milk.

Dinner: Consomme; Roast beef; Fresh

green peas; Mashed squash; Riced potato; Bread, one slice with butter; Creamy rice pudding.

2:00 P. M.: Milk, one glass.

Supper: Creamed fresh mushrooms; Baked potato; Tomato salad; Bread, one slice with butter; Canned pears; Tea with 10% cream and sugar.

8:00 P. M.: Cocoa, one cup.

Sedatives, usually potassium bromide and chloral, are given when required in order to secure sleep and rest, and all extraneous noise is excluded as much as possible. These patients are all in a special ward, the temperature of which is kept at 78° to 80° F. Nothing more than this routine is given to the average case presenting a raised blood pressure, some albuminuria and, it may be, edema.

The patient is weighed on admission and as soon as possible a complete urinalysis, blood chemistry, and blood count are done. Blood pressure readings are taken daily and special search is made for any foci of infection, and sinuses and teeth are treated when the necessity is evident.

A number of the milder cases presenting only moderately high blood pressure and slight albuminuria and edema improve rapidly under this regime and may be discharged at the end of a week or ten days. They are instructed in the home preparation of the salt poor diets. They are enjoined to rest in bed for two or three hours every afternoon, to get sufficient sleep at night, and to report once a week to the special toxic clinic. If the patient is near term she is kept in hospital until after the time of delivery.

On the other hand, there are cases which do not seem to improve materially. The blood pressure remains more or less stationary and the albuminuria persists. In practically all, the edema disappears. Whilst apparently these patients get little benefit, we cannot help believing that a number are saved from more serious conditions, especially eclampsia. This is borne out by the fact that we have had only two cases of eclampsia in the past three years among patients treated in this way.

If, on admission or after, the blood pressure is above 200 systolic and the rise has been rapid, and especially if there is edema, severe headache, epigastric pain, visual disturbances, and exaggerated reflexes, the patients are regarded as likely to develop convulsions and are given $\frac{1}{4}$ grain of morphine immediately, together with magnesium sulphate, 20 c.c. of a 10 per cent solution intravenously. The latter may be repeated in from two to twelve hours. In our experience this magnesium sulphate treatment has been followed by no untoward results and usually is effective in temporarily lowering the blood pressure, relieving the headache and, we believe, in averting convulsions. Its effects always are more pronounced in those cases of suddenly developing hypertension with the symptoms already mentioned than in those who have had a prolonged hypertension due

to definite vascular changes. Its administration, therefore, may be of diagnostic value.

In those cases with, in addition, marked edema we give hot, dry packs, surrounding the patient with warm blankets and arranging hot water bottles outside them, round the flanks and at the feet, with an ice bag on the head. The patient is put in such a pack twice a day for fifteen or twenty minutes. Colonic irrigations are given once daily. All these patients are kept constantly warm with blankets, not sheets, next to them. A very careful watch is kept; blood pressure readings are taken at frequent intervals, care always being taken not to disturb them unnecessarily. The magnesium sulphate is repeated if necessary and sedatives are continued. In the absence of definite signs of improvement the question of induction of labor or immediate delivery by cesarean section are considered. This will be taken up later.

If investigation shows the patient to be a definite nephritic and marked edema is present, magnesium sulphate, 2 ozs. every second day, is given by mouth, and the dry hot pack is used once a day. If the blood chemistry shows an increasing nitrogen retention, protein is cut down to as low as 20 gms. a day. If the urinary output diminishes, 50 c.c. of 50 per cent glucose is given intravenously every eight hours. If no improvement results, induction of labor has to be considered in the interest of both mother and child.

Therapeutic Abortion

Such is a very brief sketch of our ordinary routine treatment of cases seen in the late months of pregnancy. There remains to be considered that not inconsiderable group which we see in early pregnancy, and in which the question of therapeutic abortion arises. A patient who in the first three months of gestation shows definite signs of so called "toxemia," comes under one of two categories—chronic nephritis or chronic hypertension. In the former there is a history of some disease likely to have nephritic complication, such as scarlet fever, repeated sore throat or tonsillitis, or there is a history of "toxemia" in a former pregnancy. In some no relevant history can be obtained.

Already at the beginning of the pregnancy they show hypertension, albuminuria and, it may be, nitrogen retention. Such cases require careful study to determine whether it is wise to allow the pregnancy to continue. We must consider first the further damage likely to occur to the already damaged maternal kidneys and second, the chances of the survival of the child if the pregnancy is allowed to proceed. To take the last point first, our statistics show that out of 322 cases of nephritic toxemia of all degrees of severity, the prematurity rate was 25%, rising to 36.6% in the most severe types. This in itself means a high fetal and neo-natal death rate. Taking these premature births along with the births at term one found a total fetal mortality of

34.2% in all grades of nephritis, whilst in the severe types it is 69%. As most of these cases already evident in the early months are likely to be of the severe type in the later months we can hold out to them not more than a 50% chance of a living child. This fact must be taken into consideration in deciding for or against the continuation of the pregnancy. As regards the risk to the mother we have accumulated sufficient data to indicate that pregnancy in a nephritic is practically certain to increase renal damage and to shorten life. The indications for therapeutic abortion, therefore, are strong.

The same arguments in lesser degree apply to the hypertensive group. In 37 cases the fetal mortality was 9.7% rising to 16.7% in those cases which developed albuminuria in the later months. In those which have been followed for a period of months and years, a number have shown a high blood pressure and other evidence of cardio-vascular disease. Those that have been seen in succeeding pregnancies have had a higher level of blood pressure. We, therefore, consider a pronounced hypertension, with or without albuminuria, an indication for the induction of abortion.

Induction of Premature Labor

This may be indicated in cases of any type in which the pregnancy has advanced to beyond the period of viability and in which treatment has failed to control the condition. It also may be indicated in those milder cases of nephritis and hypertension in which, in a previous pregnancy or pregnancies, intrauterine death of the fetus has occurred before or at full term. We already have indicated that the fetal and neo-natal death rate in nephritic cases is 34.2 per cent. It is 42.8 per cent in the pre-eclamptics and 9.7 per cent in the hypertensives. A timely induction will save some of these babies, for intrauterine death usually occurs after the period viability and often just shortly before term.

These patients are not good surgical risks. They are prone to septic infection, so we hesitate to use surgical methods such as bag, bougie, or rupture of the membranes if they can be avoided. Where induction is indicated we try first of all the quinine, pituitary method. This, in our experience, is quite safe even in cases with marked hypertension, as the pituitary injections raise the blood pressure only a few points and the rise is temporary. Unfortunately, it is not always successful, especially if the pregnancy has still some weeks to go. When it fails recourse must be had to the mechanical means mentioned.

Cesarean Section

A cesarean section done prior to term always will give the baby a better chance than the induction of a premature labor. On the other hand the risk to the mother is greater. In cases where the desire for a living child is very great and in which it is inadvisable that any other pregnancy should occur, it may be

the method of election as it gives the opportunity for sterilization. In each case these advantages must be weighed against the added maternal risk. There can be no set rule, each case being judged by itself. We no longer do cesarean section or employ any other method of accouchement force in eclampsia, treating these cases according to the Stroganoff method. Our one exception is the fulminating type of eclampsia where, without any prodromal symptoms, the patient goes from one convulsion into another. Cesarean section may save the child, and apparently does not increase the maternal mortality, which is in the neighborhood of 33 per cent by any method of treatment. In the pre-eclamptic, unresponsive to treatment, we prefer the induction of labor to cesarean section, reserving the latter for those cases which present some added obstetrical indication such as an abnormal pelvis or rigid unretracted cervix.

Results of Pregnancy Toxemias

In the past three years, out of a total of 5,490 ward deliveries we have had seven cases of eclampsia. Two of these cases developed while the patients were in the wards being treated for toxemia. One patient was an emergency admission and had not been seen by us prior to her convulsive seizure. The other four were attending the prenatal clinic and nothing untoward had been noted in them at their last visits. Two of those patients had their first convulsion after delivery. All of the cases recovered.

The follow-up of our toxic cases is not yet nearly complete, as Dr. Herrick and his assistants are working on a fifteen to twenty year plan. We have followed a total of 464 toxic cases which have been delivered in the last twelve years. In them there are records of seventy-seven deaths. Forty-six of these deaths occurred some time after discharge from hospital. Fifteen of them were due to chronic nephritis, five to cerebral hemorrhage, and six to cardiac attacks—a total of twenty-six directly attributable to the toxic state. Nine deaths were from intercurrent diseases, or accident, and the cause of death in the remaining eleven could not be ascertained. When it is remembered that the great majority of those women are under thirty-five years of age this 16.5 per cent mortality is a high one. Of those that survived 36 per cent have persistent hypertension. We have records of seventy patients who had, either in the Sloane Hospital or elsewhere, a convulsive toxemia or eclampsia. Fifty-two of those have been followed. Of these fifty-two eighteen died either at the time of the seizure or afterwards, a mortality of 34.6 per cent.

These admittedly incomplete figures show that the pregnancy toxemias are serious, not only because of their immediate mortality but also because of the shortening of life from later cardio-vascular-renal disease.

620 West 168th Street

Nephritis and Pregnancy

by

K. KUDER, M.D. and H. J. STANDER, M.D.

New York, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

ONE of the most serious, and often unrecognized or neglected, complications of pregnancy is an underlying nephritis. Approximately one-quarter of our maternal death rate is due to the toxemias of pregnancy. The toxemias of pregnancy play an even more significant role in the maternal mortality, if we consider the end results following the completion of the puerperium and during the ensuing five years. Nephritis or nephritic toxemia has been regarded as one of the toxemias of pregnancy. Although an underlying chronic nephritis is, strictly speaking, not a true toxemia of pregnancy, such as vomiting, low reserve kidney, pre-eclampsia, and eclampsia, its symptomatology and clinical findings so often simulate one or other of these true toxemias of pregnancy that it is well that we consider it as a type of toxemia, in order that it may be properly recognized and treated.

When an underlying chronic nephritis in pregnancy is so considered, it constitutes almost one-quarter of all gestation toxemias, and appears as a complication in approximately three per cent of all pregnancies. By using the term "nephritis complicating pregnancy," we mean that the gravid patient has a renal disease, usually a chronic nephritis, which may have been the result of some infection, such as tonsillitis or scarlet fever, or perhaps even of repeated pregnancies. This condition is distinct and different from low reserve kidney or pre-eclampsia and eclampsia.

We should state here that eclampsia may result in chronic nephritis, just as scarlet fever may produce permanently damaged kidneys. In approximately one-fifth of eclampsia patients, this is the outcome, but, on the other hand, it must be clearly understood that nephritis plays no role in the etiology of eclampsia, in the same way as it plays no part in the etiology of scarlet fever.

Low reserve kidney usually does not result in damaged kidneys, as it is a very mild form of toxemia, clearing up under proper treatment and delivery. It is quite evident, then, that low reserve kidney, eclampsia, and pre-eclampsia are distinct entities from an underlying nephritis.

In this paper we are considering only nephritis as a complication of pregnancy. Our interest has been specifically focused on this type of toxemia as a result of a follow-up study over a ten-year period following the

diagnosis of nephritis in pregnancy. It was found that over 40 per cent of these women died within ten years after the recognition of this complication during pregnancy. We were led to conclude, after considering nephritis in nonpregnant women, that pregnancy itself hastens death in nephritic women, and that nephritis must be regarded as more serious than the other toxemias of pregnancy. The very grave prognosis has often been overlooked in that the doctor did not see or follow up his patient after the first two or three weeks of the puerperium. It was only in the five or ten-year follow-up study of these patients that we obtained a true index of the severity and prognosis in this complication.

Types of Nephritis

In order to understand the significance of an underlying nephritis during pregnancy, we must have an appreciation of the various types of nephritides. Many classifications have been suggested, although, at present, it is generally accepted that there are three main forms: the hemorrhagic or glomerular type; the nonhemorrhagic arteriosclerotic or nephrosclerotic type; and the non-hemorrhagic degenerative type, also known as nephrosis, lipid or amyloid.

The first of these, glomerulonephritis, has an acute onset, either heals, improves to a latent stage, or, passing through a chronic stage of lesser or longer duration, which is usually edematous, ends in uremia. Volhard and Fahr further subdivide the glomerular type into diffuse and focal forms, the latter being recognized by its normal blood pressure. It is a disease of glomerular inflammation.

The second type, the arteriosclerotic or nephrosclerosis, has an insidious onset with marked hypertension and usually no, or very slight, edema. Later in this disease the patient may develop edema. In this type, the heart becomes involved, and death occurs from cardiac failure, apoplexy, or uremia. In this disease, the arterioles are affected, their lumina being contracted as a result of endarteritis and intimal hyperplasia. There may be a certain amount of glomerular destruction but no marked tubular degeneration.

In the third type, the degenerative or nephrosis, the onset may again be insidious, with marked edema and albuminuria, but no hypertension. The disease may end in cure or ultimately involve the glomeruli and the patient may die from uremia. The significant pathology in this type is a degenerated tubu-

lar epithelium. In the description of these types we have followed the excellent monograph of Van Slyke and his coworkers who have added so much to the better understanding of these forms of nephritis.

Chronic Nephritis in Pregnancy

Rarely do we see an acute glomerulonephritis complicating pregnancy. The degenerative type, or nephrosis, although also very rarely seen, appears more frequently than the acute stage of glomerulonephritis. The usual form of nephritis complicating pregnancy is the chronic, either of an arteriosclerotic origin or following an acute or latent glomerulonephritis. The latter, also known as active chronic hemorrhagic nephritis, corresponds to Volhard and Fahr's nephrotic type of glomerulonephritis and to the so-called hemorrhagic chronic parenchymatous nephritis of the older writers. The arteriosclerotic type of nephritis or the nephrosclerosis of Volhard and Fahr is believed to occur more frequently than any other form of nephritis, and may be benign or malignant. The first clinical sign of the disease is hypertension with or without slight albuminuria. The benign form may continue as such for many years, the patient ultimately dying from circulatory rather than renal failure. In the malignant form, a decrease in renal function makes its appearance, death may occur from renal failure.

Undoubtedly, the majority of pregnant patients suffering from an underlying chronic nephritis fall into the nephrosclerosis group of Volhard and Fahr. The outstanding clinical features of this disease are the hypertension, slight albuminuria and cardiac enlargement, while in the chronic stage of a hemorrhagic or glomerulonephritis, the outstanding features are edema, a marked decrease in kidney function, slight or microscopic hematuria, and only slight hypertension with or without marked albuminuria. As it is not always easy or necessary to differentiate between the types of a chronic nephritis during pregnancy, we advocate the use of the term "chronic nephritis during pregnancy" and shall so refer to all our cases of an underlying chronic nephritis recognized during pregnancy, except where the findings clearly indicate a nephrosis.

Statistics in Cases of Toxemias of Pregnancy

In this paper, we are presenting a study of all patients suffering from a chronic nephritis during pregnancy, who have been under care and treatment in the Woman's Clinic of the New York Hospital. The incidence of nephritis, the infant and maternal mortality, type of treatment, and the results obtained are considered. This study included patients having been seen in this Clinic over a six months' period beginning September 1, 1932. During this period, 1443 patients have been discharged from our

obstetrical service, and of this number 178 were discharged before delivery. There were 203 patients treated for a toxemia of pregnancy, of which 45 had chronic nephritis. Our figures may be presented as follows:

Total obstetrical patients discharged 1,443
Total toxemia patients discharged 203
Incidence of toxemia 14.067%

Of the 203 toxemia patients—

40 were discharged before delivery
163 were discharged after delivery

Of the 40 patients discharged before delivery, diagnoses were as follows:

Low reserve kidney	12
Chronic nephritis	10
Unclassified	13
Vomiting of pregnancy .	5
	<hr/>
	40

Of the 163 toxemia patients discharged after delivery, the diagnoses were as follows:

Low reserve kidney	97	59.50%
Chronic nephritis	35	21.47%
Unclassified	15	9.20%
Pre-eclampsia	11	6.74%
Eclampsia	3	1.85%
Vomiting of pregnancy	2	1.22%
		<hr/>	
			163

Statistics in Cases of Chronic Nephritis

A study of 29 patients suffering from a chronic nephritis, shows that 23 of these were white and 6 colored. The age distribution was as follows:

16-20 years	3
21-25 "	8
26-30 "	10
31-35 "	7
36-40 "	1

Four of these patients were discharged before delivery and have not been delivered up to the present time. One patient was admitted from the year-return clinic. The ante-natal care was good (meaning the patient had visited the antenatal clinic three times or more) in 22 cases; defective in 4 cases, and 2 patients had never been seen in the antenatal clinic previous to admission to the Hospital.

All of these patients had negative Wassermann reactions and gave no history of anti-luetic treatments. Two patients had a further complication of chronic valvular heart disease. Seven patients had a history of a previous toxemia of pregnancy, 2 having had eclampsia, 2 others severe vomiting of pregnancy, and 3 a toxemia of unknown type. Fourteen of the patients of this group were

gravida 1, the others were distributed as follows:

Gravida 2	4
" 3	4
" 4	1
" 5	2
" 6	0
" 7	1
" 8	1
" 9	1

The types of delivery were as follows:

Spontaneous	18
Operative	11
Forceps	2
Labor induced by bougie	2
Breech extraction	2
Classical cesarean section	1
Classical cesarean section + tubal sterilization	2
Abortion, spontaneous	1
Abortion, therapeutic (subtotal hysterectomy)	1

The duration of labor was less than 20 hours in all except 1 case of 47 hours. The duration of the second stage was less than one hour except in 2 instances, and in both of these cases the patient was delivered by forceps. The puerperia were for the most part uncomplicated. One patient developed pyelitis and 6 had mild puerperal infections.

Out of the 22 full term and premature deliveries, there was 1 stillbirth, a macerated premature infant weighing 1880 grams. All the other infants were discharged from the hospital in good condition. Five had weighed less than 2500 grams at birth. There was one set of twins. There were no maternal deaths.

Antenatal Care

The importance of having patients regis-

ter in an antenatal clinic early in their pregnancy is readily understood for better care can be given the patients. It also makes it possible to determine when the signs or symptoms of toxemia first appear. The number of visits made to the clinic, previous to delivery of the 29 patients studied, ranged from 1 to 18. In the cases under consideration, the blood pressure was 140/90, which we consider as the upper limit of normal, or above in 7 patients at the time of their first visit to the antenatal clinic; and of these, 3 were in the first half of their pregnancy. In the remaining cases followed in the clinic, 3 patients showed an elevation of blood pressure in the first half of pregnancy. In patients suffering from definite kidney disease, the blood pressure rises above normal earlier in pregnancy than it does in the other types of toxemia.

Not only is the blood pressure taken on each clinic visit, but a urine analysis is also done. Nine of the patients showed no albumin in the urine, but in the other cases the amount varied from a trace to 2 grams or over. A note is made of the amount of edema present. The weight of the patient is also taken on each visit.

On each visit the patients were carefully questioned as to symptoms. The common complaints were headache, dizzy spells, blurring of vision, vomiting, constipation, and edema. Attempts were made to regulate the patient's diet by having a dietitian interview each patient and instruct her regarding a proper diet.

Hospital Care

If the patients showed no improvement under the treatment possible in the out-patient clinic, they were admitted to the Hospital. Seven of the patients had admissions to the Hospital and were discharged during their antenatal period; several others were so ill that, following admission, they could not be discharged before delivery.

On admission to the Hospital, the patients are immediately put to bed and placed on a special diet (low protein diet with salt intake limited to 2 grams). In addition to the routine examination, a careful ophthalmoscopic examination of the eye grounds is made. If necessary, the pupils are dilated with homatropine. Eight of the 29 patients had retinal edema, a few showed tortuosity of the vessels, while the remainder were essentially normal. Daily urine analyses are made to determine the amount of albumin, and microscopic examination is carried out. It was found that 9 of the 29 cases showed the presence of hyaline and granular casts in the urine. The response of the blood pressure to rest in bed and treatment is followed daily.

In Figure 1, we present in a graphic manner the findings in the hospital of a typical case of chronic nephritis complicating

FIG. 1

nancy. The patient entered the hospital with a markedly elevated blood pressure, albuminuria, and kidney function tests below normal. Rest in bed and proper diet failed to produce marked improvement. An abdominal hysterectomy was performed during the twenty-second week and the patient kept in the hospital three weeks following the operation. Her subsequent course, as found at follow-up visits and shown on the chart, indicate a definite chronic nephritis. It should be pointed out here that the blood chemistry is not of great diagnostic or prognostic value, except in the very severe cases showing nitrogenous retention.

In Figure 2, we show the blood pressure findings, both systolic and diastolic, in 2 patients suffering from chronic nephritis. This chart shows clearly the course of the disease as seen by the hypertension.

Kidney Function Tests

The function of the kidneys is routinely investigated in these patients, as well as frequent blood chemistry determination made. The kidney function tests performed are the creatinine excretion test, urea clearance test, and the fifteen-minute phenolsulphonphthalein test. The results of these examinations on the patients are recorded at the time of admission to the hospital, at the time of delivery, during the puerperium, on discharge from the hospital, and some time later during the postpartum course.

The technique of these tests is not complicated and easily performed. The phenolsulphonphthalein test is performed by obtaining specimens of urine every fifteen minutes for a two hour period, after injection of an ampule of the dye intravenously. The percentage of the dye excreted is recorded under eight columns and the total excretion given in the last column. A curve drawn in comparison with the normal, gives a clear picture of the variations. (See Figure 3.)

RESULTS OF SEVERAL PHTHALEIN TESTS

	1	2	3	4	5	6	7	8
Normal	140	16	8	6	4	2	2	0
Chronic nephritis								
No. 706	4	10	11	0	4	5	7	9
No. 781	4	7	6	5	6	4	3	3
No. 2267	12	15	9	6	4	3	2	0

From this table it will be seen that the excretion of the dye is delayed in appearance and greatly reduced in amount.

RESULTS OF UREA CLEARANCE TESTS

	1	2	Average
Normal	88.4	116	102.2
Chronic nephritis			
No. 8060	51.2	60.8	55.8
No. 2267	65.1	56	60
No. 781	33.5	35.7	34.4

The creatinine test is performed by collecting the urine for one hour, then injecting intravenously 0.5 gm. of creatinine. The amount of creatinine excreted in the urine during the first and second hours after the injection is compared with the creatinine content of the urine before injection. Again the results are best recorded in a graph. (See Figure 4.)

RESULTS OF SEVERAL CREATININE TESTS

	Before Injection	1st hour	2nd hour
Normal	90	230	120
Chronic nephritis			
No. 3267	64	126	100
No. 10073	34	126	86
No. 11936	25	106	146

In a normal individual, the excretion of creatinine at the end of the first hour should be three times that of the fasting or first specimen, and that at the end of the second hour should be twice that of the fasting specimen. An excretion below this indicates decreased kidney function.

It must be pointed out that a single determination of any one of these three kidney function tests is of very little value. Repeated determinations of the same test, as well as of one or both of the other tests, are essential to correctly interpret the kidney function in any given patient. We have not mentioned the Addis' cell count test, which is of value in certain of the nephritides, especially in the active chronic hemorrhagic type.

Treatment

Our views regarding treatment have undergone radical changes. In face of a maternal mortality of over 40 per cent, when it is calculated on a ten-year basis, we feel that treatment should be less conservative than has been heretofore practiced. We do not hesitate to advocate termination of pregnancy in a patient in whom a definite diagnosis of chronic nephritis is firmly established. Pregnancy, as it proceeds towards term, throws a greater and greater strain on the kidneys and undoubtedly shortens the lives of women suffering from an underlying nephritis. If the patient is near term and the child living, we usually advocate cesarean section with sterilization, as we cannot depend greatly on birth control. One cannot be radical in all patients, as each case has to be studied individually. The general principle on which sound treatment is based is the knowledge that chronic nephritis and pregnancy form an exceedingly serious combination, and that the continuation of a pregnancy or a subsequent

—York Ave., & 69th Street.

pregnancy may materially aggravate an underlying nephritis.

Conclusions

1. In 1443 obstetrical discharges from our clinic, there were 203 cases of toxemia of pregnancy, an incidence of 14.067 per cent.

2. Nephritis complicating pregnancy constituted 21.47 per cent of all toxemias of pregnancy.

3. The greatest number of pregnant patients suffering from an underlying chronic nephritis fall in the age group 26 to 30 years.

4. The fetal mortality in patients with nephritis is 4.54 per cent in this small series.

5. The immediate maternal mortality in patients with nephritis gives an erroneous impression of the gravity of this complication, as in a ten-year follow-up study, Stander and Peckham found a maternal mortality of 42.5 per cent.

6. Frequent antenatal examinations in all pregnant women is essential if we are to recognize, early, an underlying nephritis.

7. Hospitalization with careful study is necessary in all suspected cases of chronic nephritis, in order that a correct diagnosis may be made, the kidney function carefully evaluated and the proper treatment instituted.

8. Of all kidney function tests, we advocate the fifteen minute phenolsulphonaphthalein, the urea clearance, and the creatinine excretion tests.

9. The blood chemistry is only of value where the nephritis is so severe as to be accompanied by nitrogenous retention. A normal blood chemistry does not rule out a chronic nephritis.

10. In view of the grave prognosis in nephritis complicated by pregnancy, we advocate fairly radical treatment, consisting of termination of pregnancy with sterilization in a certain percentage of these cases. However, each case has to be studied individually before one can determine the procedure of choice.

National Institute for the Deaf in England Frames a New Code of Ethics

Complaints have been made in England by the National Institute for the Deaf that manufacturers of hearing aids have exploited and victimized the deaf by selling them devices unsuited to their particular needs and hence of no value to them whatever. Even the extremely deaf have been induced to buy instruments that turned out to be of no service, and often all financial refunds or readjustments

have been met only with refusal.

The Institute has framed a code of ethics to end these abuses, which dealers are asked to sign, and a growing number of journals now decline to take advertisements from firms which do not accept it. Benefit societies and other social welfare bodies are demanding similar pledges, before aiding the purchase of instruments.

Treatment of Carcinoma of the Cervix

by

WILLIAM P. HEALY, M.D.,

Gynecologist, the Memorial Hospital

New York, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 5, 1933.

CARCINOMA of the cervix, for the present at least, seems to be regarded as a lesion in which radiation therapy offers a better chance of relief of symptoms, prolongation of life and possible cure than can be obtained by surgical measures.

By this statement we do not mean to imply that surgeons have been won over to radiation therapy for all cases, as we are well aware that hysterectomy is still done by a few and no doubt to the patient's advantage in some instances.

Occasionally a surgeon operates because there are no adequate radiation facilities available. At other times because the patient objects strenuously to radiation and insists upon operation. Rarely, however, is the operation of the Wertheim type with complete removal of parametria and a long vaginal cuff. As a rule it is a simple panhysterectomy and can be regarded only as palliative rather than curative.

Actually only ten to fifteen per cent of the cases are seen sufficiently early, while the disease is still limited to the portio vaginalis of the cervix, to permit of satisfactory and thorough surgical removal.

Unless the hysterectomy is of the Wertheim type, an operation unfortunately associated with high morbidity and mortality, it will be of little permanent value in curing the disease, even in the early cases.

Radiation therapy came into use in an effort to solve the surgeon's problem and to permit him to save not only the favorable cases but to do something worth while for the seventy-five to eighty per cent of advanced and unfavorable cases which are not at all amenable to surgical cure, or even to a simple vaginal or abdominal hysterectomy. Such a procedure in an advanced cervical cancer is futile as the operative incisions pass directly through cancer-bearing structures and in a few weeks a rapid recurrence of ulcerating carcinoma appears at the vaginal vault, so that it is then difficult to believe that the cervix really had been removed. Such recurrences are extremely difficult to treat with any degree of success, even with radiation, as the removal of the uterus deprives us of our only chance to place radium safely in the center of the cancer-involved tissues and to deliver to them an effective radiation dose, one that may reasonably be expected to cause complete regression of all cancer growth in the field of

radiation without destroying important normal structures. We are therefore strongly opposed to hysterectomy when it can be avoided in advanced cervical cancer.

On the other hand, the presence of pyometra may compel us to do hysterectomy. Mild degrees of pyometra with only a small quantity of thick, yellow, nonodoruous exudate in a uterus of average size need not interfere with radiation and often will disappear in course of treatment. When, however, one meets with a foul-smelling exudate in an enlarged uterus with a dilated cavity, the case requires different management. In such cases we usually apply radium against the cervix by means of a vaginal applicator for 1000 to 2000 millicurie hours. After this treatment we dilate the cervical canal sufficiently to permit the placing of a rubber drainage tube the diameter of a lead pencil into the uterine cavity. This usually is kept in place for a week during which time the cavity is flushed out daily with mild antiseptic solutions. As soon thereafter as it seems safe, a radium tandem is placed in the cervical and lower uterine canal for the usual dosage of 3000 millicurie hours. It is difficult to say what the optimum time is for doing this, it may be one or two weeks after drainage was instituted or it may be later or in some cases it may never be feasible. When the pyometra is extensive and does not respond to drainage we believe hysterectomy (supracervical) is indicated whether or not one has been able to finish the planned radiation.

From time to time in carrying out routine radiation in cervical cancer, we meet with what properly may be called radiation-resistant cases. In such instances after completion of the full course of radiation with radium and x-rays, we observe that the lesion and the cervical tissues instead of cleaning up and diminishing in size are larger, swollen, rigid and really more bulky than before treatment was started.

It is quite evident that there has been no regression and indeed no satisfactory response to radiation. If six weeks after treatment such a condition exists we believe panhysterectomy, if at all feasible, is indicated as further radiation would only result in necrosis, ulceration and fistula, whereas the hysterectomy may permit complete healing of the vaginal vault and thereby protect the patient from foul discharge and hemorrhage while she lives. Of course such a procedure is only palliative, is recognized as such and is not

planned to cure the patient of cancer. With the occasional exceptions referred to we believe hysterectomy has little or no place in the routine treatment of cervical cancer.

At first radiation for cancer was carried on to some extent with roentgen rays alone but it received its greatest impetus from the discovery of radium in 1898.

Carcinoma of the cervix was one of the first of the major cancer lesions to be attacked systematically by treatment with radium. The response to treatment was so satisfactory that the method rapidly spread throughout the world. The chief difficulty at first was the scarcity of the element and its high cost. In recent years additional large radium bearing deposits have been found and the cost of radium has gone down considerably. Its use has become more widespread and there is a more accurate knowledge of its therapeutic value and limitations.

Etiologically it is felt that there must be a close association between cervical trauma incident to dilatation of the cervix in labor and the subsequent development of carcinoma in the cervix, as 90 per cent to 94 per cent of the women in our series have been pregnant and have given birth through the cervix. It would seem therefore that careful observation and treatment of benign cervical lesions subsequent to pregnancy might be an important factor in diminishing the incidence of cervical cancer.

Schmidt's clinical classification of cancer of the cervix into four groups is an excellent one. Unfortunately very few cases are seen sufficiently early in their course, while the disease is still limited to the cervix and without any enlargement of it, to be placed in group one. Such cases when seen should result in 75 to 85 per cent five year cures.

Because of the infrequency of such cases we combine Schmidt's groups one and two in to one group which we call early or favorable and in which we may expect about a fifty per cent five year cure rate. Although the term borderline group still is used by us we gradually are dropping it and placing the cases either in the early group or in the advanced group in which there is a 15 to 20 per cent chance of obtaining a five year cure. All other extensively diseased cases are placed in the palliative group in which we do not expect them to survive five years.

Our classification then consists of (1) an early or favorable group, (2) an advanced or unfavorable group, and (3) a palliative group.

Such classifications are subject to error due to the personal equation of the physician as is evidenced by the fact that some of our supposedly early cases die within one year after treatment is given and an occasional so called palliative case survives five or more years.

It becomes difficult, therefore, to correlate

statistics from different clinics because of unavoidable errors in the assignment of cases to different groups. We believe, therefore, that the ultimate test of any method of treatment may reasonably be based upon the total five year salvage of all cases treated by that method.

It is interesting to note that most of the clinics with well organized departments of radiation obtain 20 to 25 per cent total salvage of all cervix cases. This means that only one out of every five cases seen can expect to survive five or more years.

This is certainly a very discouraging situation, and one deserving every effort on our part toward improvement.

Of course, the earlier the diagnosis the greater the chance of effecting a cure. But earlier diagnosis seems out of the question until all women who have borne children can be induced to resort to periodic pelvic examinations at intervals of nine to twelve months in order that suspicious changes in the cervical tissues may be detected and checked up by biopsy if necessary. The important and only symptom which attracts the patient's attention is the unexpected appearance of bleeding from the genital tract. Often this is observed only in association with intercourse or following a vaginal douche, so called contact bleeding. It is self evident that by the time sufficient disease is present to cause enough ulceration and destruction of tissue to permit obvious bleeding, the disease cannot be regarded as early for no doubt lymphatic contamination and spread have already occurred. Thus early diagnosis must rest upon visual observation and biopsy by the physician.

Carcinoma of the cervix, histologically, in a series of 1574 cases reported by us, was of the squamous epidermoid type in 97.3 per cent of the cases. The remaining 2.7 per cent were of the glandular or adenocarcinoma type.

As we have said before the earlier the diagnosis the better the prospect of a cure and this is true regardless of the histologic type of cancer present.

However in the more advanced cases we believe that other things being equal the less mature cancer cell, so called embryonal or anaplastic cell type of tumor, is more radiation sensitive than the tumor composed of fully developed adult squamous cell structure and therefore under radiation therapy gives a much better prognosis than under surgical treatment.

Since about 80 per cent of cervix cases are made up of the more radiation sensitive cell types it would seem that this probably accounts for the satisfactory response of the primary lesion to treatment.

Under the plan of treatment at present in vogue on the Gynecological Service in the Memorial Hospital we find that the primary

lesion in and about the cervix will disappear in four to six weeks in practically every instance, in which the response is satisfactory. In general the cervical lesion does not give us much concern for we know we can dispose of it in all but the most advanced and hopeless cases. But we must not let this deceive us.

It is the cancer that has invaded other pelvic structures distant from the cervix that will ultimately and with much coincident pain and distress terminate the life of the patient unless we can do something to eliminate it. When one depends for cure upon radium alone, placed in the cervical canal, he should realize that cancer cells more than one and a half inches away from the applicator used rarely will receive enough effective radiation to cause their disappearance. By using vaginal applicators as well as intrauterine, the tissue dose of radiation in the parametria can be somewhat increased but it is doubtful if we can obtain enough radiation effect two inches (5 cm.) away from the cervical canal to eliminate cancer at or beyond that point.

With this in mind we have resorted, consistently and as an important part of our routine treatment of all cervix cancer cases for the past eleven years, to external radiation of the entire pelvic field with roentgen ray directed through two anterior and two posterior portals.

For the past seven years this has been done with 200 K. V. machines and for four years we have in all but the earliest or most advanced cases given the x-ray cycle first and delayed the radium applications until ten to fourteen days after the x-ray cycle is finished.

This routine is regarded by us as important and possessing many advantages in all ulcerated, advanced cancers. The lesions are

usually infected, there is considerable pelvic lymphangitis, the patients are suffering constitutionally from toxic absorption. Such infected lesions are not desirable or favorable sites for the application of radium.

With our routine of x-ray first, the appearance of the primary cervical lesion changes markedly, the superficial fungating infected surface disappears, the surrounding edema subsides, the lesion is smaller and the uterus acquires more mobility. We have prepared the lesion and the adjoining tissues so that they are in much better condition to respond satisfactorily to radium applications and there seems to be less constitutional and pelvic disturbance with or following the radium treatment.

Our plan of treatment, which has been described many times, is called the "cross-fire radiation method" and consists of (a) a high voltage x-ray cycle of four treatments 700 R units each, (b) 10 to 14 days later radium is applied to the vaginal surface of the lesion by means of vaginal applicators for 1000 to 2000 millicurie hours, (c) the following day under anesthesia two radium capsules in tandem formation are placed in the cervical and supracervical canals for 2000 and 1000 millicurie hours respectively, (d) eight weeks following the first x-ray cycle a second similar x-ray cycle is given.

During treatment and until the cervical lesion is entirely healed the patient is advised to use vaginal douches, once or twice daily, of potassium permanganate solution. Interstitial radiation with needles or seeds is not used as part of our routine treatment but may be used as a later treatment for any portion of the lesion that fails to completely regress, but this is not often necessary.

French Academy of Medicine Wages Campaign in the Interest of Public Safety

THE French Academy of Medicine is waging a campaign for the examination of automobile drivers, in the interest of public safety, but is encountering opposition from interests that fear it would interfere with the sale of cars.

Thirty-six taxi drivers who have had accidents were examined by a physician and ten were affected with dementia paralytica, twelve with psychasthenia linked with impulses and obsessions, two with alcoholic dementia, two with epilepsy, two with toxi-comania, four with alcoholism and three with dementia praxicox.

Another physician addressed the Convention on the Safety of Highways and urged that

driving permits be refused to persons with serious nervous troubles, those suffering from hysteria, epileptics, psychopaths, and chronic alcohol addicts. The convention was cold to these proposals, however, we are told, and the daily press refused articles on the subject through fear of offending automobile advertisers.

Some hope is felt that the accident insurance companies may take a sympathetic attitude as it is to their interest to eliminate drivers who cause accidents, but any reduction in the number of drivers would also cut the number of accident policies and premiums, so even the insurance companies cannot be counted upon.

The Treatment of Tumors of the Ovary

by

HOWARD C. TAYLOR, JR.

Associate Gynecologist, Roosevelt Hospital
New York, N. Y.

THE problem in the treatment of ovarian tumors is quite different from that of the uterine growths which have just been discussed. In the case of cancer of the cervix and of the corpus and, to some extent, in that of uterine fibroids, one is dealing with a relatively homogeneous group of tumors whose course can be predicted with some certainty as soon as their presence is detected. With cancer of the uterus, furthermore, the disease itself is so grave that no consideration need be given the further function of the reproductive organs. For the treatment of such tumors generalizations are possible and the problem of therapy is readily reduced to a decision between rival forms of technique.

The special difficulty in the treatment of ovarian tumors arises from the existence of many types which differ widely in their tendencies for further growth and for the development of certain complications. The particular requirement in the treatment of these tumors is, therefore, an additional step in diagnosis for the differentiation of the many special types and with this an adequate knowledge of the potentialities of each. It is only with this information that one can select a form of treatment which will permit every possible conservation of function and at the same time avoid the preservation of organs which may be a source of future danger to the patient.

The extent of treatment required in a given case of ovarian tumor is dependent upon four variable characteristics which may be listed as follows:

1. The tendency to develop to a great size is an important consideration in deciding the first question of whether or not to operate. Certain of the small, non-neoplastic cysts will remain relatively stationary or will regress, while others, such

as the pseudomucinous cysts, will almost inevitably reach enormous proportions.

2. The tendency to develop various complications, particularly torsion, represents a hazard of varying importance among the different types of even the benign tumors and under certain circumstances is a reason against delay in operating.

3. The tendency to bilateral development must be the chief guide in determining the advisability of limiting the operation in a given case to the removal of only one ovary.

4. The frequency of the malignant transformation of benign tumors remains a disputed question. Percentages, however, are offered in the literature based either on the cases in which malignant areas are found within otherwise benign tumors, or on the proportion of the malignant to the benign growths among tumors of supposedly similar histogenesis.

Due allowance must be made for an age variation which will justify in young women a slightly greater risk of future trouble in the interest of the conservation of the ovarian function. Nevertheless, on the basis of the four considerations just noted, one may attempt a somewhat arbitrary classification of ovarian tumors according to the extent of the treatment required. The classification to follow is based on statistics drawn in part from cases treated on the Roosevelt Hospital Gynecological Service, in part from already published series from other institutions.

Non-Neoplastic Cysts and Endometriosis

A. The corpus luteum and follicle cysts are in most cases temporary structures present during one menstrual cycle or persisting for only a few months. (See Table 1.)

Table 1—NON-NEOPLASTIC CYSTS AND ENDOMETRIOSIS

	Size	Bilateral Development	Malignant Transformation	Complications
Follicle and Corpus Luteum Cysts.	Small. Spontaneous disappearance.	Frequent.	Never.	Menstrual disturbances. Hemorrhage, rare. Pain.
Endometrial (Chocolate) Cysts.	Usually small. Spontaneous regression after menopause or operation.	33% in present series.	Doubtful (Theory of Sampson—10).	Adhesions. Intestinal obstruction. Dysmenorrhea.

Table 2—METHODS OF TREATMENT OF ENDOMETRICAL CYSTS OF OVARY, 1926-1930

	Ages 26-39		Ages 40-52	
	<i>Uterus normal</i>	<i>Fibroids</i>	<i>Uterus normal</i>	<i>Fibroids</i>
Hysterectomy Bilat. Salp.-ooph.	2	4	3	6
Hysterectomy Unilat. Salp.-ooph.	0	2	0	1
Unilat. Salp.-ooph. Partial oophorectomy.	5	0	0	0
Unilat. Salp.-ooph. (My- omectomy in 4 cases).	5	4	0	0

On account of the relative frequency of these minor cystic enlargements of the ovary, the treatment in young women of cysts under three inches in diameter should properly be begun by a period of observation before surgery is undertaken. If such cysts are found after the abdomen is opened, the maximum operation should be the enucleation of the cyst or a partial oophorectomy. Under two special circumstances there is an opportunity for intelligent conservatism. In patients in whom cysts of the ovary are found after a previous gynecologic operation, a second should certainly not be undertaken till the pathologic findings at the first have been ascertained, for such recurrent cysts will as a rule prove to be of this harmless type. A less common problem is found in the multiple corpus luteum cysts occurring in association with hydatidiform mole which also tend to disappear spontaneously after the cure of the uterine disorder. Care should be taken to avoid the mistake of operating on the ovary instead of the uterus as was done in a case reported in the last year (Moroudis).

B. The teaching that endometriosis is due to implantations usually widely spread

throughout the pelvis and that these implants are dependent upon ovarian activity for their growth, has resulted in a tendency to radicalism in the treatment of this disease to produce a suppression of the ovarian function. Several recent reports, however, notably one by Seitz (11) of Frankfurt, indicate that at least symptomatic cures may be expected by relatively conservative operations. I have reviewed the thirty-two cases of endometriosis of the ovary treated at the Roosevelt Hospital from 1926 to 1930 and in Table 2, the extent of the operations is indicated. This table shows also that the type of treatment of this disease often depends, not upon the extent of the endometriosis itself, but upon the presence of associated fibroids. In the absence of these tumors it was necessary in young women to remove the uterus in only two of twelve cases, while even with fibroids as a complication, four uteri were preserved by means of a myomectomy combined with removal of a unilateral endometrial cyst. None of these cases have required further treatment so that a conservative approach to endometrial lesions of the ovary is now our rule. Treatment of endometriosis by a partial or a complete cas-

Table 3—COMMON BENIGN TUMORS—PREDOMINANTLY UNILATERAL

	<i>Size</i>	<i>Bilateral Development</i>	<i>Malignant Transformation</i>	<i>Complications</i>
Pseudomucinous Cysts.	Very large.	Unusual: 1.08% (4) 4.6 % (7) 5.6 % (13) 6.8 % (12)	1.9%(9) 5.6% (4) 6.7% (13)	Torsion: 11.53% (4) 27.4 % (13) Rupture. Pseudomyxoma: 2.07% (13) 5.6 % (4)
Dermoid.	Moderate size.	Infrequent: 8.0% (12) 9.8% (4) 13.1% (7) 18.4% (13)	6% (13)	Torsion: 9.4% (4) 18.0% (13) Perforation. Suppuration.
Fibromas.	Variable.	Rare: 0% (13) 2% (4) 13% (12)	Sarcoma?	Torsion: 36 % (5) 3.6% (3) Ascites.

Table 4—PAPILLARY CYSTADENOMA—STRONG BILATERAL TENDENCY

	Size	Bilateral Development	Malignant Transformation	Complications
Papillary Serous Cystadenomas.	Moderate size.	19% (13) 27% (12) 30% (14) 60% (9) Coarse Pap: 17% (4) Fine Pap: 50% (4)	Unproven but perhaps frequent. 45.2% (13)	Torsion: 10% (13) 8% (4) Ascites. Peritoneal implantations.

tration dose of x-ray has been advocated (Albrecht 1) but should not be employed unless the diagnosis is first established, which rarely is possible until exploratory laparotomy has given surgery the first opportunity to cure the disease with preservation of the ovarian function. X-ray in endometriosis has its chief place therefore in recurrent cases, or cases with persistent symptoms after a conservative operation.

Benign Tumors Predominantly Unilateral

A second group of neoplasms which as a rule occur as unilateral cysts are usually treated by removal of the affected ovary only. This rule may be varied to permit the preservation of a little of the affected organ in young women, or the prophylactic removal of even the apparently sound second ovary in women after or near the menopause. (See Table 3.) These tumors include the dermoid, the fibroma and the pseudomucinous cyst. The presence of any one of these tumors forms a definite indication for surgical intervention, for various types of complications such as great size, torsion, suppuration and pressure on surrounding organs are common. Disease of the second ovary is infrequent, however, and malignant change is rare.

Benign Tumors with Bilateral Tendency

One group of tumors, usually classified as benign, has a strong tendency to bilateral development and apparently a close relationship with the malignant growths. These are the papillary cystadenomas. In the Roosevelt Hospital series (14) approximately a third were bilateral and in four cases disseminated peritoneal implants were present (see Table 4). The special liability of the opposite ovary to be involved and the difficulty of distinguishing these papillary tumors from the papillary cystadenocarcinomas, sometimes even under the microscope, makes special care in their handling necessary. In all cases in which a conservative operation is contemplated, microscopic examination by frozen section should be made if possible before the abdomen is closed and in all doubtful cases, particularly in women over thirty-five years of age, both adnexa should be removed. This probably is more essential in certain forms, notably those with slender papillae and those

with papillae on the outside of the cyst than in the other type with coarse, sessile growths on the inner surface.

The cases with papillary implants on the peritoneum deserve special attention. I have recently reported four such cases (15) in which spontaneous regression of these implants has apparently occurred since the patients have remained well over long periods in spite of an incomplete removal of the growth by the surgeon. Such cases have been reported fairly frequently and afford some hope for a few patients who at first appear to have a hopeless prognosis. The possibility of this type of growth being present should therefore be considered before any case is given up as inoperable.

Carcinoma of the Ovary

At three stages in the treatment of a case of ovarian carcinoma decisions must be reached as to the course to be followed. (1) When the patient is first seen, whether an operation is to be performed; (2) when the abdomen is open, how extensive an operation is to be

undertaken, and (3) after the operation is complete, whether x-ray is to be given.

1. *Operability.* In many cases of ovarian cancer a definite diagnosis is not arrived at till the abdomen has been opened so that one must recognize laparotomy as usually the first procedure. This should not, however, be the invariable approach because, as Table 5 shows, the surgical exploration of advanced cases is accompanied by a high mortality rate.

Attempt should be made therefore, to eliminate two categories from the group to be operated upon. (1) In all cases of apparently malignant ovarian tumor the possibility of the growth being secondary in the ovary must be thought of, x-rays of the gastro-intestinal tract made, and operation given up when any other lesion besides the ovarian is discovered.

Certain very advanced cases with ascites, exia, large pelvic tumors and upper ab-

dominal masses are readily recognizable as inoperable and these cases should have their treatment limited to external radiation.

2. *The extent of the operation.* When at the time of operation the growth is found apparently confined to one or both ovaries, there is a general agreement that a complete hysterectomy should be performed, with the removal of both appendages. The preservation of an apparently uninvolved ovary is rarely to be considered, for as Norris (8) has recently shown, in 17.5% of such cases the grossly normal ovary is later found in the laboratory to contain foci of cancer cells. The preservation of the uterus as a holder for the later use of radium has been recommended (Heyman 2), but this procedure has not met with wide approval and should not be employed except in the advanced cases. Radiation from this source is too limited in its scope to outweigh the danger of retaining an organ with possible metastasis.

Table 7
RESULTS OF TREATMENT OF CANCER OF THE OVARY, 1910-1927

Total Cases—84. Five year cures—7.
Absolute cure rate—8%.

	Alive	Dead or Recurrent	Untraced

Extension to omentum ..		6	1
Extension to uterus and tubes		2	4
Operable			
Bilateral ...	2	4	1
Unilateral ..	5	5	8
Total	7	63	14

The extension of the operation to the removal of single metastatic lesions from organs outside of the pelvis is a dubious procedure. Only in the case of an isolated metastasis in the omentum whose removal does not increase the severity of the operation to an appreciable degree, is such a procedure justifiable and one patient so treated at the Roosevelt Hospital was in good health when last seen four years after her operation. Resection of part of the bladder or intestine was carried out in a few of the earlier cases and proved both futile and dangerous.

When cancer is found widely disseminated on the pelvic or general peritoneum, a question arises as to whether any surgical procedure should be carried out. Such a condition was found in approximately half of the Roosevelt primary cases. It has been our practice under such conditions to remove as much of the tumor tissue as possible, partly because of the temporary palliation, partly because of the improved psychological effect on the patient resulting from the disappearance of visible evidence of tumor, partly because a persistent although perhaps unfounded belief exists that x-ray may be more efficient when directed at smaller masses of tissue.

3. *Postoperative Radiation.* In view of the bad results obtained by the simple surgical treatment of ovarian cancer, postoperative radiation therapy should be given in practically all cases. This opinion is held as a result of favorable reports from outside sources although our own series shows no cures and no increase in the average duration of life attributable to x-ray or radium therapy. (See Table 6.) The relative failure in this series is very likely dependent upon inadequate dosage.

The absolute five-year cure rate in this series of cases amounted to only eight per cent (Table 7). These unfavorable results find their explanation in the fact that two-thirds of the cases were actually inoperable upon their admission to the hospital. An increase

in the number of cures is here as elsewhere largely dependent upon better diagnosis but the prospect of an earlier recognition of tumors situated deep in the pelvis in relatively functionless organs is not a hopeful one.

In conclusion the initial premise of this paper may be restated. When tumors of the ovary are considered as a whole, the problem of their treatment is not primarily a technical one but one of differentiation of the special types. It is only by the recognition of the varied potentialities of the members of the group that treatment can be decided upon which will give the patient the greatest possible chance for preservation of function with, at the same time, the least risk of further trouble as a result of ill considered conservatism.

Gifts to Columbia

Recent gifts to Columbia University for medical purposes include the following:

Rockefeller Foundation, \$29,374 for various purposes; \$6,000 for aid of studies of the common cold.

General Education Board, \$4,583.33 toward maintenance of the department of the practice of medicine; \$8,000 toward support of the sub-departments of tropical medicine.

Edward S. Harkness, \$9,967 toward support of the department of diseases of children.

Josiah Macy, Jr., Foundation, \$8,462.50 for the work of various departments.

Eli Lilly and Company, \$2,400 for research in the department of pathology.

Commonwealth Fund, \$18,000 for research into causes of dental decay.

W. K. Kellogg Foundation, \$10,000 for study of rheumatic fever under the direction of Dr. Walter W. Palmer.

National Research Council, \$5,000 for special research in the department of anatomy.

The Treatment of Uterine Myomata

A Review of 500 Cases

by

ROBERT A. KIMBROUGH, JR., M.D.,

Philadelphia, Pa.

From the Dept. of Gynecology, Hospital of the University of Pennsylvania. Read by invitation at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 5, 1933.

NO lesion of the female pelvis requires more careful individualization in the choice of treatment than a uterine myoma. In some clinics operation is the method of choice in all cases, while others employ irradiation to the exclusion of surgical measures. We believe that both of these plans are to be condemned, each method has its advantages and limitations; each patient presents a different problem, and the choice of operation or irradiation can be determined only after judicious consideration of all factors concerned. This decision can be made only by the gynecologist who is familiar with both forms of treatment. Accuracy of diagnosis is essential. Too frequently the gynecologist is consulted only after irradiation has failed to effect satisfactory results in patients ill suited to this method of treatment.

We share the commonly accepted belief that many myomata require no treatment. This applies particularly to small symptomless tumors in women who are approaching or who have passed beyond the menopause. Cessation of ovarian function will be followed by regression and even complete disappearance of the tumor in most instances.

The larger number, however, require treatment because of abnormal bleeding, pressure symptoms or associated pelvic pathology. This report is based on a review of the methods of treatment employed and the end results obtained in 500 consecutive cases from the service of Dr. Floyd E. Keene in the Hospital of the University of Pennsylvania.

Dr. John G. Clark adopted the use of radium in the treatment of myomata in 1913. During these years careful follow-up studies have been made of patients treated by both irradiation and operation. As the result of this experience, certain definite rules have been formulated which guide us in the selection of treatment for the individual case.

The following conditions are ideal for the use of radium: a patient above the age of 45 who has a tumor not larger than a three months' pregnancy, the only symptom of which is profuse menstruation.

We believe that radium is contra-indicated under the following conditions:

1. Tumors Larger Than a Three Months' Pregnancy:—Extensive degenerative changes are frequent in larger tumors because of their inadequate blood supply. Irradiation may

further impair their nourishment to such an extent that these changes are accelerated. Large tumors are often complicated by adnexal lesions, the detection of which may be impossible prior to operation. Such tumors frequently so distort the uterine cavity that a complete diagnostic curettage is precluded; under these circumstances an area of corporeal carcinoma may easily escape detection. While regression of myomata commonly occurs following irradiation, the larger tumors, in our experience, do not often completely disappear. The etiologic relationship between myoma and carcinoma of the fundus has not been definitely established but there is evidence to suggest that the presence of myomata may be a factor in the development of endometrial malignancy. In his discussion of fundal carcinoma, Graves stated that fibromyomata were associated with 25.7% of his cases.

For these reasons we believe that surgical removal of larger tumors is the more conservative procedure.

2. Rapid Increase in Size:—Rapid enlargement of a tumor is due to some form of degeneration. This may be either benign or malignant, and in both, operation rather than irradiation, is indicated.

3. Pressure Symptoms:—Symptoms referable to pressure on the bladder or rectum can be relieved only by removal of the tumor. Regression of the tumor following irradiation is slow and it may be insufficient to relieve the pressure. Under these circumstances operation is preferable.

4. Tumors Associated with Pelvic Pain:—Pain in association with a myoma indicates some complication and is usually due to one of the following conditions: chronic adnexitis, degeneration of the tumor, adenomyoma, or endometrial cysts of the ovary. The application of radium may light up a quiescent inflammatory adnexal lesion and should be avoided when the history or pelvic findings suggest its presence. This complication was found in 25.9 per cent of our cases. For previously stated reasons, degenerating tumors should not be subjected to irradiation. In our experience adenomyomata do not respond satisfactorily to irradiation; this is confirmed by Kelly and Burnham who state that in the treatment of such tumors "radium is of no avail." Again pain may be due to an associated endometrial cyst of the ovary, the treatment of which usually falls in the domain of surgery. While it may be impossible to de-

termine the exact cause of pain prior to laparotomy, the conditions revealed at operation will practically always justify the choice of surgical treatment.

5. *Pedunculated Tumors, Both Subperitoneal and Submucous*:—Radium is useless in the treatment of pedunculated subperitoneal tumors. In the submucous type necrosis may occur or irregular bleeding may continue.

6. *Profound Anemia*:—Radium should not be used in the presence of a severe anemia. Such patients react poorly to it, and their lowered resistance increases the possibility of necrosis and infection of the tumor.

7. *Uncertain Diagnosis*:—The prime requisite for successful irradiation is accuracy of diagnosis. If examination under anesthesia does not reveal the exact nature of the pelvic pathology, operation is the preferable procedure.

8. *Stenosis or Blockage of the Cervical Canal*:—Radium should be applied to the body of the uterus well above the internal os; otherwise it may lead to partial or complete stenosis resulting in pyometra or hematometra.

9. *The Presence of Marked Secondary Anemia in Association with Tumors Not Giving Rise to Sufficient Uterine Bleeding to Account for the Anemia*:—Several such cases have come under our observation. In each, careful studies failed to demonstrate the cause of the anemia, and at operation extensive necrosis of the tumor was found. Rapid improvement of the anemia following operation warrants the conclusion that the degeneration was responsible for it.

10. *Tumors in Young Women*:—Irradiation in sufficient dosage to cause disappearance of the tumor will be followed by a premature menopause which often is associated with marked nervous manifestations. Patients under the age of 45 should be treated surgically in order that ovarian function may be preserved.

11. *Extremely Nervous Patients*:—The chief objection to radium therapy is the high incidence of severe menopausal symptoms. Such reactions occur more frequently and are of longer duration in the highly nervous woman than in the more phlegmatic type. In such individuals we believe that hysterectomy with conservation of ovarian function is a more conservative procedure than irradiation and will yield better end results.

12. *Previous Pelvic Operation*:—We do not favor the use of radium in patients who have had a previous pelvic operation because of the possibility of serious damage to an adherent loop of intestine. In such cases we prefer operation or roentgen therapy.

13. *Fear of Radium*:—Not infrequently patients have an unwarranted fear of the effects of radium. If we are unsuccessful in convincing the patient that her fear is unfounded, we prefer to operate even though the pelvic condition be ideally suited to irradiation. When radium is used in spite of this fear, many subsequent complaints may unjustly be ascribed to its lasting effects.

By close adherence to these indications and contra-indications we have used radium in only 22.8 per cent of the cases in this series. Reports from our clinic show a steady decrease in the relative number of patients treated by radium. This decline in percentage of irradiation treatment does not mean that we are losing faith in the method, but rather that the contra-indications are being more rigidly observed.

Radium never should be applied without a preliminary diagnostic curettage. By this means valuable information is obtained in regard to the exact location of the tumor, and the possible presence of an associated corporeal carcinoma will not escape detection.

We formerly considered twelve hundred milligram hours of radium the standard dosage for the treatment of myoma. This dosage proved to be excellent in the control of bleeding and in securing regression of the tumor, but it was followed by a rather high percentage of severe menopausal symptoms. During the past five years the dosage has been reduced to 600 to 900 milligram hours. The incidence of severe menopausal symptoms has diminished, bleeding has been controlled and there has been satisfactory reduction in the size of the tumors. Should, however, the smaller dosage be insufficient one safely can resort to roentgen irradiation, since the possibility of fundal carcinoma has been eliminated by the curettage which was performed at the time the radium was applied.

In this series a fifty-milligram capsule of radium element has been used with a filter of 0.5 millimeter of platinum and 2 millimeters of soft rubber tubing. During the past year the platinum filter has been increased to 1 millimeter. With the higher filtration there is practically no local devitalization of the endometrium and the incidence of troublesome post-irradiation leucorrhea has been eliminated. The radium is placed within the body of the uterus well above the internal os and is fixed in place by suture and firm vaginal packing.

The results following radium treatment, in so far as control of bleeding and tumor reduction are concerned, have been satisfactory in 95.9 per cent. Only four patients have required more than one application; radium was used again with excellent results in three of these, and the fourth responded well to roentgen treatment. Subsequent hysterectomy was required in four cases because of per-

sistent bleeding. At operation two of these patients were found to have pedunculated submucous tumors which accounted for their failure to respond to radium. The operative findings in the two remaining cases are not known.

Menopausal symptoms were absent or only mild in 60.8 per cent of patients treated with radium; they were of moderate severity in 22.6 per cent, and were severe in 16.5 per cent.

Results of Radium Treatment

No. cases treated with radium	109
No. cases followed	97
Result excellent in regard to control of bleeding and tumor reduction	93.8%
One treatment required	89.7%
Two treatments required	4.1%
Bleeding controlled but not stopped	2.1%
Failure (subsequent hysterectomy required)	4.1%
Satisfactory results obtained	95.9%

Menopausal Symptoms

None	31.9%
Mild	28.8%
Moderate	22.7%
Severe	16.5%

Roentgen Irradiation

Although only thirty-three of our patients were treated by roentgen irradiation, we believe that this form of therapy has a definite place in the treatment of myomata. Patients whom radium is contra-indicated and who, for local or constitutional reasons, are poor operative risks, may be safely and satisfactorily treated with x-ray. This applies particularly to profoundly anemic patients with large tumors, or with smaller tumors complicated by pelvic inflammatory disease. The bleeding in such cases can be controlled by roentgen therapy, appropriate measures can be used to combat the anemia, and if operation is subsequently necessary, it can be performed under more favorable conditions. The majority of patients so treated will not require operation, but there are others in whom unsatisfactory regression of the tumors renders their removal advisable.

Roentgen treatment may be used with comparative safety in tumors associated with adnexitis and is of great value in cases in which operation is contra-indicated because of obesity, cardiovascular disease, pulmonary complications and thyrotoxicosis.

As a general rule, diagnostic curettage should precede roentgen treatment. Occasionally, however, anesthesia in any form is undesirable; in these cases curettage may be omitted with reasonable safety, provided there has been no intermenstrual bleeding suggestive of malignancy.

Since Murphy has shown the high incidence of microcephalic idiocy and other congenital malformations following postconceptional ir-

radiation, it is most important that patients avoid conception in the intervals between roentgen treatments. Preliminary curettage will prevent the unwitting irradiation of an unsuspected early pregnancy.

It has been our plan to use only the amount of irradiation necessary to induce permanent amenorrhea. This has varied from a minimum of 250 r. to a maximum of 540 r. in the ovarian region, the majority of the patients requiring between 300 and 400 r. The factors used were as follows: 200,000 volts, 50 centimeters distance, 0.5 millimeter of copper plus 1 millimeter of aluminum filter, giving a skin dosage of 800 r. over each portal, the number of portals varying with the thickness of the patient. One series of treatment was sufficient in the majority of the cases, although one required three series and another four series before permanent amenorrhea was induced.

Bleeding was satisfactorily controlled in 93.5 per cent of the patients subjected to roentgen irradiation and reduction in size or complete disappearance of the tumor occurred in 86.9 per cent. While the results in these respects were excellent, severe menopausal symptoms occurred in 25 per cent of this group. These symptoms were moderate in 37.5 per cent, mild in 25 per cent, and absent in only 12.5 per cent. This study shows that the menopausal reaction following roentgen treatment is even more severe than after bilateral oophorectomy, and this constitutes a formidable objection to its employment in a larger proportion of cases.

Surgical Treatment

The Clark Clinic always has advocated conservatism in the management of uterine myomata, and this applies with particular emphasis to the surgical treatment where conservation of normally functioning organs should be carried out wherever possible.

We are not in favor of vaginal hysterectomy as a routine procedure, although this operation may be ideal in the occasional patient who presents a small tumor with considerable relaxation of the pelvic floor.

Obviously vaginal myomectomy is indicated when a pedunculated tumor projects from the cervical canal. In this series only eight patients (1.6 per cent) were suited to this form of treatment. We have been able to follow the subsequent course in five of these. There has been no recurrence of menorrhagia and no additional tumors have formed.

Abdominal myomectomy is unquestionably the ideal operation in the young woman, in whom it is desirable to maintain procreative as well as menstrual function, but we believe that it is unwise to employ this method unless the preservation of a normally functioning uterus seems assured. Unfortunately in this series only twenty patients were found amenable to myomectomy.

The end results following myomectomy were satisfactory from the standpoint of menstrual

function in 82.3 per cent. One patient required subsequent hysterectomy because of persistent bleeding. In fifteen patients procreative function was preserved and pregnancy has occurred in only one of these.

If hysterectomy is decided upon, two questions at once arise: first, shall the hysterectomy be complete or partial, and second, what shall be the disposition of the ovaries? We realize that the first of these questions is controversial, but we believe that, with few exceptions, supravaginal amputation is the operation of choice. Reports from several clinics indicate that total hysterectomy is not attended by increased mortality or morbidity, but these results do not apply to the operation as performed by the majority of surgeons.

The fact is indisputable that carcinoma of the cervix may develop after a supravaginal hysterectomy, but this is comparatively rare, and we are convinced that the increased mortality and morbidity attendant upon the universal adoption of total hysterectomy would far exceed that incident to subsequent carcinoma of the cervical stump. The incidence of carcinoma can be largely eliminated by cauterization or repair of the diseased cervix as a preliminary step to the supravaginal operation. In a recent review conducted in our clinic extending as far back as 1910, during which time several thousand supravaginal hysterectomies were performed, only three patients are known to have developed carcinoma of the retained cervix. These occurred eleven, twelve, and eighteen years, respectively, after the original operation.

Our clinic always has advocated conservation of ovarian function wherever possible, for, by so doing, distressing menopausal symptoms are avoided in the great majority of cases. Of the patients treated by hysterectomy in this series, one or both ovaries were conserved in 60 per cent. In this group 82.5 per cent had no menopausal symptoms and in only 3.9 per cent were these symptoms severe. On the other hand, severe menopausal symptoms were present in 25 per cent of the cases following bilateral oophorectomy and were absent in only 20.2 per cent of this group.

Ovarian conservation is important also from the standpoint of the preservation of regular menstruation in young women who require a supravaginal hysterectomy. In patients under forty-five years of age we attempt to conserve sufficient endometrium to permit of regular, though lessened, menstruation. Following this plan regular menstruation has occurred after supravaginal hysterectomy in 19 per cent of the patients under 45 years of age; in none of these has the bleeding been profuse; with the exception of two patients in whom the reaction was mild, none of these have developed menopausal symptoms. These results indicate that there may be a reciprocal relationship, possibly hormonal in nature, between the endometrium and the ovary, and

they offer clinical confirmation of the experimental work of Sessums and Murphy. These workers have shown that hysterectomy in the rabbit is followed by inhibitory and degenerative changes in the conserved ovary, and that these changes are limited by the autotransplantation of endometrium.

The end results following hysterectomy were excellent in 96 per cent of the followed cases. In 4 per cent pelvic pain or bladder symptoms persisted after operation.

Postoperative Mortality and Morbidity

Irradiation was not attended by morbidity or mortality. Six patients, however, died following operation, giving an operative mortality rate of 1.8 per cent. Convalescence following myomectomy was uneventful in every case.

The hysterectomy group has been subdivided into uncomplicated and complicated cases. In the latter group we have included large intraligamentous tumors and those associated with large ovarian cysts, chronic adnexitis and ovarian endometriosis. The mortality following hysterectomy in these cases was 3.35 per cent, and in the uncomplicated cases the rate was 0.6 per cent.

Pulmonary embolism was the cause of death in four patients, occurring on the fifth, sixth, eleventh, and fourteenth postoperative days, respectively. One patient died of cerebral embolism on the eleventh day following a difficult operation for a large intraligamentous tumor; autopsy proved the remaining death to be due to massive atelectasis of both lower lobes associated with chronic myocarditis.

Morbidity was present in 10.9 per cent of the operative cases. Femoral phlebitis occurred in seven cases, an incidence of 1.2 per cent. Nine patients had sudden onset of pleuritic pain which was thought to be due to small pulmonary emboli. Massive collapse of the lung occurred in three cases. Complete intestinal obstruction developed in two patients, four and seven months, respectively, after hysterectomy. Both recovered after release of adhesive bands.

Summary

Five-hundred consecutive cases of myoma uteri are reviewed from the standpoint of treatment and end results. The indications for irradiation and operation are discussed.

Radium was employed in 22.8 per cent, with satisfactory results in 95.9 per cent. There were no deaths following, irradiation.

Röntgen irradiation was used in 7.0 per cent. Bleeding was controlled in 93.5 per cent and tumor reduction was satisfactory in 86.9 per cent.

The high incidence of severe menopausal reactions is the outstanding objection to irradiation therapy, and the administration of menopausal dosages to women under the age of 45 is to be condemned.

Surgical treatment was the method of choice in 70.2 per cent. The operative mortality was

1.8 per cent. The results following hysterectomy were excellent in 96.0 per cent of the followed cases.

Conclusion

Irradiation is not to be looked upon as a

Myopia

(Special Article)

A metropolitan newspaper recently commented upon the fact that too many people wear glasses and left the impression that myopia was not a condition which needed particular care. This statement cannot pass unchallenged for it is at variance with professional knowledge and evidence. Such a pronouncement gives the patient a false sense of security and leads to inaction on the part of those responsible for the health of children.

Myopia is a common condition which is often hereditary and may be present at birth. Several years ago an investigation was made to determine its incidence in the various school age groups. It was found that there was a very definite progressive rise in the number of afflicted patients between primary and high school periods, from high school to college and from college to university. Continuous application to close work seemed to be one of the factors involved in its production.

High degrees of myopia are often hereditary. Both eyes of the patient may be highly myopic or one eye may have practically normal vision. This hereditary factor is well established and those predisposed to the disease should have the benefit of modern medical science to prevent or at least alleviate the ravages of this handicapping ocular malady.

As there are several rather well-defined types of myopia and as the medical adviser of the family is the one to whom the children should be taken for advice and counsel, it is imperative that he should have a working knowledge of the types of myopia so that he can recommend the appropriate treatment, and thus be prepared to offset the possible ill-effects of the newspaper comment.

The first class comprises a large number of children who have difficulty in seeing their black-board lessons. Most of these show a slight but definite yearly increase in the degree of the myopia.

The second class includes those in whom poor distance vision is discovered and found to progress so rapidly that correcting glasses must be changed

every few months. These patients should be kept under the strict surveillance of a competent ophthalmologist. Two groups can be segregated in this class. In the one, progress of myopia is almost completely arrested in early adolescence. In the other more alarming symptoms develop. The patient becomes extremely short-sighted with a tendency often to development of a stretching of the eyeball which causes a tearing of the retina in the macular region, and a permanent impairment in reading vision, or a detachment of the retina. These serious cases are sometimes referred to as malignant myopia and demand the most enlightened form of treatment.

The third class comprises those who in middle or late life find that as a result of a developing near-sightedness they are unable to see in the distance as clearly as formerly but that they can do their near work more easily. This is the result of a change in the lens of the eye which may be the earliest sign of incipient cataract or the first evidence of a constitutional disease, especially diabetes.

Myopia, is then, a real medical problem.

While each patient is an individual and must be so treated, certain hygienic measures tend to delay or check the progress of the disease. Among these are suitable light, proper position of the head, controlled use of the eyes, medical treatment and corrective glasses.

The child must be trained to use his eyes for close work only when sufficient daylight is available or where the artificial illumination is ample. He must further be instructed to hold his head as erect as possible and have the light come over his left shoulder. A near-sighted child should not do close work for more than half an hour at a time.

In the rapidly progressive types of myopia excessive near work should be prohibited. Some ophthalmologists believe that myopia can be held in check by certain drugs such as adrenalin. All eye physicians are agreed that the greatest deterrent to the progress of myopia and the most efficient treatment is the constant use of proper corrective glasses.

EDITORIALS

Salutatory

New hands take over the editorial and business direction of THE NEW YORK STATE JOURNAL OF MEDICINE with this issue. The task has been entrusted to us by the Medical Society, and it shall be our sole aim to perform it in such a way as may best serve the interests of the members.

It is a task at once sobering and inspiring. To carry on the work and traditions of the Medical Journal of a Society which has been in existence 125 years, seems almost beyond ordinary human powers; yet at the same time the very prospect of assisting the many thousands of physicians of this Imperial State to interchange their best thought and information for the furtherance of their mission of healing is enough to fire the enthusiasm of anyone fortunate enough to be given such an opportunity.

The new editorial and business management accepts its commission in this high spirit. Whatever is helpful to the best practice of medicine will find a place in its pages. No other branch of science is advancing with more rapid strides than the science of medicine, and it shall be our purpose to keep THE JOURNAL in the very forefront of the best authentic scientific progress.

Not for a moment, either, must it be forgotten that this journal exists primarily and solely for its readers, the members of the Society. If they find it helpful, it will succeed; if not, it will fail. No editor or publisher can make it succeed alone. So we appeal to the rank and file of the membership of the Society to aid us by their advice and friendly co-operation. If you find some feature helpful, tell us about it; if you

find something to criticize, tell us about that, too. Praise and blame are both helpful.

A publisher of a great national magazine once sent its editor to visit the subscribers in the cities and towns, to sit with them by the fireside, to talk intimately with them about the magazine, and to find what they liked or disliked in it. That is what the editor and publisher of THE NEW YORK STATE JOURNAL OF MEDICINE would like to do with its readers. In the rush and hurry of today, that is impossible, but many a good visit can be made by letter, and it is our earnest wish to make the acquaintance, in this way, of the splendid men who are fighting the great battle against disease and death in New York State. If our efforts prove helpful to them in this warfare, it will be a reward beyond anything that mere words can say.

Unified Action

The coming session of the Legislature is fraught with manifold possibility of danger to the profession of medicine. We are living in troublesome times; a revolution is going on—thus far peaceably—in the whole world and its effects in this country are even now striking, and the future is clouded by uncertainty.

These are the times of the demagogue and the mob; none know this better than the men and women of the profession. These are the times of the propagandist and the quack in politics; of the nostrum peddler in government; of the panaceaist in sociology; of the opportunist in society; of the great voice attached to the small mind. And the Legislature in the end is moved by voices—which seem to mean votes—in a democracy.

It has been tritely said that government in the modern democracy is carried on by organized minorities; this is just as true today as it was in the Florence of the Renaissance, the Rome of the Caesars, the Athens of Pericles, or the Egypt of the Pharaohs and as it will be in the Utopia of the millennium.

The profession of medicine as a group has been organized—loosely it must be admitted—but it has not been unified, apparently, and never will be until it meets a major emergency which threatens its social effectiveness and its professional ideals; it is merely in the process of "becoming." Its voice is potentially mighty—mightier now than ever before—when it is raised in the true cause of man's welfare and is as one voice. Unfortunately it has not, as yet, one voice. Legislatures listen to one voice; not to a series of cacophonous bleatings. The profession of medicine to develop its full social effectiveness,

which in the end is evidenced by the legislation governing the people, must reconcile whatever differences may exist among its members so that it can speak with one voice; rationally, honestly, faithfully and wisely, and, because of its age long experience, justly, for the whole people.

But to effect its proper social purpose, maintain its own liberty, preserve its own dignity and conserve its own function in the biology of society the profession of medicine must not alone be organized—it must be unified. Only thus may it save the people from baneful social medicine and itself from subjugation.

James J. Rooney, M.D.

Alfred Fabian Hess

Dr. Alfred Fabian Hess was born in 1875 and died suddenly on December 5, 1933, in New York City. He was graduated from Harvard University in 1897 and from the College of Physicians and Surgeons in 1901. Dr. Hess spent two years in post-graduate study in Europe and returned to the United States in 1903 to practice pediatrics and pursue scientific medical investigations. Hence the period of Dr. Hess' active professional career in New York covers thirty years. Within that relatively short span of years he made himself an internationally recognized authority on scientific and clinical aspects of pediatrics and enriched medicine with discoveries the high significance of which is widely and generally recognized. Dr. Hess, therefore, is to be classed with that remarkable group of scientifically endowed clinicians, not as numerous as distinguished, who amid the claims of medical practice yet find opportunity and time for the advancement of knowledge through research.

The name of Dr. Hess is most intimately associated with the fruitful investigation of the deficiency diseases of early childhood, and especially with the elucidation of the nature of rickets and scurvy, and the discovery of ready means for their prevention and alleviation. It is in large part because of Dr. Hess' imaginatively conceived and accurately conducted clinical and experimental studies that our knowledge of these diseases has reached a high degree of perfection, and that measures based on this knowledge give promise of the gradual and permanent suppression of these affections.

We may well turn to Dr. Hess' Harvey Lecture of 1921 in order to discover the thesis which determined the direction of his important and successful studies of the next twelve years, until he was so suddenly and prematurely stricken in the fullness of his remarkable powers. Dr. Hess opens the lecture by stating

that "one of the most novel medical conceptions is that serious diseases or functional disorder may be occasioned by a mere lack of certain constituents of the dietary," adding to the earlier view that tissue damage arises from harmful agents, chemical or biological, introduced from without. The newer concept was already implicit in the results of Eijkman's feeding experiments on fowl with decorticated rice, and Hopkins' tests on animals with chemically purified food constituents. While these observations led to the discovery of the essential part in the dietary played by vitamins, it was Dr. Hess' many and ingenious studies which laid bare the mechanism of the antirachitic agencies and carried the observations derived from experiment on animals to their fruitful application in clinical pediatrics. If from the invaluable investigations made by Dr. Hess we desire to select the one which gave a new direction to scientific medicine, it would be that relating to the effects of ultraviolet light on the production and prevention of rickets, the climax of which was the discovery of ergosterol, obtained from yeast, as the chemical substance which is activated and made biologically potent by radiation. That food stuffs can also be made antirachitic was determined by Dr. Hess, and that both sunlight and the carbon arc lamp are preventively and curatively effective in children was also demonstrated by him.

Dr. Hess enriched medicine by discoveries in other fields, as is indicated by the working out of a protective serum therapy for mumps, and the preparation of a hemostatic tissue extract to which he gave the name of thromboplastin.

The absorption of Dr. Hess in problems of nutritional disorder in his last period arose from the great advances being made in the knowledge of that subject, from the recognition of its increasing importance under the conditions of modern life, and by reason of the essential part which his researches were playing in the elucidation of phenomena still obscure.

Simon Flexner, M.D.

Food and Drugs Act

Some twenty-seven years ago Congress adopted a food and drugs act to protect public health and prevent deception, which was considered a model of its kind and resulted in many benefits. In the intervening years deficiencies and weaknesses gradually became apparent which were enhanced by the more intense advertising and high-pressure salesmanship of our day, and resulted in an increasing defeat of its intended purpose. Also

during this period there developed the almost universal use of new food products, such as ice cream containing sixty percent of air, and cosmetics, which are not included in its scope.

The absolute need for revision of the law has long been recognized, the work on the details by the Food and Drug Administration of the U. S. Department of Agriculture has been under way for several years, and the New Food and Drugs Bill (S. 1944, H.R. 6110) is now ready to be submitted to Congress. It presents all the advantages of the present law, is intended to prevent the modern abuses which have developed since and to eliminate the deficiencies which have become apparent.

While foods and drugs may now bear no false statements or exaggerated claims on their packages, there is no control whatever on the advertising matter describing them in print or on the radio. Even so, in order to now prove only misbranding it must be shown that the manufacturer knows the statements are false, obviously a most difficult thing to do. The new law covers not only the branding but also the advertising in any form, and it is particularly specific in preventing curative claims for drugs by prohibiting statements which directly or by ambiguity claim effect in any of a long list of symptoms and diseases, which includes particularly those for which extravagant claims are now common in current advertising. As cosmetics, including x-ray and radium used for beauty purposes, are at present not controlled by the food and drugs law, irresponsible use and false labeling and advertising are common, and dangerous poisonous preparations are on the market. While local departments of health have controlled the dangerous cosmetic situation in the larger centres, federal restriction is imperative for general safety and is fully provided for in the proposed new law.

Though the present law prevents the addition of poisons to foods, better control is needed to prevent the sale of dangerous foods regardless of what constitutes the hazard. As some foods are susceptible of dangerous contamination by the unsanitary surroundings in which they are packed, the new law demands permits after inspection in the cases in which such danger may exist.

The new law not only prohibits false labeling as before but also requires statement of the whole truth. Foods must carry their common names and drugs the common name of each therapeutic or physiologically active ingredient. The penalties for violation in the new law are much heavier and injunction proceedings are also possible. Formerly the light penalties were often simply considered as license fees by unscrupulous persons.

The public hearings on the proposed new law will doubtless bring about changes in the present draft, but it is to be hoped that the proposed protection of public health will not suffer thereby. The matter should have the earnest attention of the medical profession and all the support it deserves.

Frederic E. Sondern, M.D.

Medical Sensationalism in the Press

The latest victim of medical sensationalism is Dr. James Ewing, the eminent director of the Memorial Hospital in New York City. Dr. Ewing made an address on cancer before the International Cancer Congress in Madrid in October, and in it he remarked that "the idea of discovering a single cure for all cancers is absurd." Imagine his amazement to find on his return home that he had been represented in the newspapers as saying that "the idea of discovering a cure for cancer is absurd." Again, Dr. Ewing pointed out that repeated exposure of the skin to wind and sunlight, if carried to excess, may cause some cancers of the skin or cause chronic changes in the skin of some subjects which will later lead to cancer of the skin. The reporter, of course, had to parade this as an attack on nudism. "The word nudism does not appear in my paper," declares Dr. Ewing, in a public statement of protest.

Other statements in his address were also twisted out of all recognition, with the effect, he declares, that they "seem to have caused so much disturbance to cancer patients and to many physicians that an effort toward correction is demanded. The confusion," he adds, "seems to have arisen from the tendency to make sensational news out of a serious and somewhat technical discussion."

This is one case out of many, and Dr. Ewing's eminence enables him to get his protest published. In other cases, the truth never succeeds in catching up with the error. Every physician will recall seeing medical "news" in the daily press which he knows at once is absurd. The doctor usually smiles wearily and shrugs his shoulders. But, as Dr. Ewing remarks, these false reports unsettle the minds of the public, and fill the hearts of sufferers with doubt and fear. If every piece of medical sensationalism and yellow medical journalism brought a storm of criticism from the doctors of the community, newspaper editors and reporters would write with more care and caution, and, in cases of doubt, would call a physician on the phone and get the right slant on the subject before plunging into some absurdity. The remedy lies in the hands of the doctors. The weary smile and the shrug of the shoulder are not enough. We can fight the devil with fire,

and fight the pen of error with the pen of truth,
and may the right win!

William Seaver Woods.

Whither Our Hospitals?

The modern hospital as it exists today is an outstanding contribution to social progress. In fact, no aspect in the field of public health represents as much wholesome benefit to the community as the hospital structure in the United States. The voluntary hospitals have participated in the tremendous industrial development of the last thirty years. It would be surprising if hospital development had not paralleled the same evolution as occurred in industry. If in similar degree the hospitals benefited by the tremendous prosperity of America they also today suffer from the depression that affects all lines of business endeavor. The voluntary hospitals have been created and maintained from the philanthropy of public-spirited citizens and with the drying up of such sources of revenue many of the voluntary hospitals have been forced to the expenditure of some of their unrestricted endowments and many of them are frankly insolvent. There is no immediate prospect that the so-called large givers to hospitals will be in a financial condition to assist the hospitals. Rigid economies have been instituted and yet the receipts are insufficient to meet the expenses for maintenance.

It is also apparent that for many years hospital management by and large has been extravagant. The experience of the United Hospital Fund in New York City in regard to hospital and dispensary accounting cost leaves the impression that many hospitals have conducted their finances on an ineffective system and are unable to allocate costs to their many sub-divisions. Of more importance, however, in the hospital situation is the lack of foresight in planning hospital facilities and in exploring possible sources of revenue for their maintenance. It is not necessary that every voluntary hospital have every specialty in the domain of medicine or surgery. By the same token it is not necessary for every hospital to maintain accessory departments which, while useful, are after all luxury services and quite distinct from the main, primary purpose of a hospital. Perhaps the greatest defect of modern hospital policy has been the constant and increasing extension of the dispensary service. The amount of sickness at any given time in any community, barring epidemics, can be calculated upon the known verity of the law of probability so that the sum total of illness at a given time can within reasonable limits be computed.

The spirit that has animated hospital executives

in their desire to extend free dispensary service or a dispensary service at a very minimal admission fee has resulted in a constantly increasing increment of deficit. Many of the voluntary hospitals embrace services that are uselessly repetitive. Many of them have subdivided their services into such a finely spun division of specialism that by no stretch of the imagination can that service be worth the disbursements entailed. Since there should be no profit-making element in hospital management the policy should be to provide an adequate and competent service in keeping with the demands for such service by the worthy poor.

It is rather an irony that hospitals not having to pay for the most expensive item in industry, namely, their technical professional service, are unable to maintain a balanced budget.

The problem before the community is the maintenance of their voluntary hospital system. The maintenance of this hospital system is not primarily the responsibility of the physicians but is the obligation of society. By the same token it is incumbent upon Boards of Trustees of hospitals and the executives to inquire if their particular institution is not carrying an overload of needless expensive services. In the too liberal extension of these services and in the fatal inability to cancel their dispensary services for individuals who can and should pay lies the greatest bankruptcy factor.

It would appear that two essentials must be complied with if the voluntary hospital system is to carry on:

(1) a restriction of the dispensary service along the following lines:

- (a) absolutely free service to the indigent;
- (b) a service charge to be assessed upon certain minimal income groups;
- (c) a charge sufficient to pay for the service those individuals above the basic minimal group;

(2) fair and adequate compensation to physicians working in the dispensary.

Failure of hospital authorities to rationalize income and disbursements or failure to control the type, character and quantity of service rendered will mean further gradations in insolvency, with a possible appeal for income from the tax receipts. If the voluntary hospitals in any way become dependent upon the tax receipts it will imply, and for all practical purposes mean, some supervision by the predominant political party, with a breakdown in the quality and character of the services rendered. A further extension of this political domination would mean the hiring of the attending physician staff on the basis of politics and would fasten upon the community

the principle that one doctor is as good as another, which is false.

The problem of the hospital can be solved, but not by expecting a return of prosperity sufficient to recreate a large group of liberal givers. Greater social benefits can be conferred upon the community if more and better business methods are introduced into hospital management. A hospital may render important, effective and worth while service and yet not engage in luxury service. A hospital may be more effective in its social usefulness by curtailing some of its activities rather than extending them. An exaltation of charges in the hope of a larger revenue may defeat the very thing for which the additional charges were contemplated. An unchecked and unrestrained dispensary service may wreck a hospital that can function more adequately to the community on a less extensive scale.

Medical charity founded on the expectation of liberal benefactors is largely a thing of the past. In the future hospitals will require more effective management, fewer executives, less repetitive services in order that the institution may function to the fullest possible extent for the community. An estimated hospital deficit for the United States for 1933 of seventy million dollars, with the prospect of twenty-five million additional deficit in 1934 as a result of the sales and processing taxes, presents a problem of gigantic proportions for the trustees of hospitals as well as the community.

Charles Gordon Heyd, M.D.

"Doctors Say"

This magic phrase now crops up everywhere, in advertising on the air or on the printed page. It seems to assure us that if we drink the right coffee, tea, chocolate or fountain drink, if we eat the right breakfast food, use the right mouth wash, chew the right gum, or eat the right peanuts, then our systems will be filled with vitamins. P. D. S. or R. S. V. P., disease will be unknown, and our old age will flourish with a vigor unknown since the days of Methuselah.

Claims as lurid as a summer sunset are cleverly buttered over by the statement that 'doctors say' or 'physicians agree' that this marvelous product will flood the frame with the happy glow of youth. Just who the doctors are who say all this is neatly dodged, but of course the innocent public never notices it.

Medical journals around the country are beginning to discuss this sort of hocus pocus, and it is to be hoped that when people wake up to it, it will be laughed out of court. Probably little real harm is done if people use these products and imagine health is thrilling through their veins,

and it is really a little bouquet for the medical profession, when the mere words, "doctors say," will sell a million dollars' worth of this or that.

It seems that this particular brand of buncombe has gone even further, and has used the names of prominent physicians without their consent. Suppose that Dr. Medicus of the Highbury Medical School publishes a paper in a national medical journal saying that calcium and phosphorus are required in normal metabolism. Promptly, the wily manufacturer comes out with the statement that "Our fountain drink fully meets the health requirements in calcium and phosphorus declared necessary by Dr. Medicus." The eminent doctor is aghast, he can protest, he can forbid further use of his name, but the damage is done. The organ of the Iowa State Medical Society publishes a long editorial on this growing abuse. Vigorous protests sent to the manufacturers by physicians everywhere will show them what the doctors say' and will stop this evil.

William Seazer Woods

A "Five-Year Program" to Control Tuberculosis

Have we been lulled into a false sense of security by the cheering figures showing the decline in tuberculosis?

It seems that the death rate from pulmonary tuberculosis in the United States has dropped from 187 per 100,000 population to 68 in 25 years and has dropped from 100 to 68 in ten years. In New York State it has dropped from 152.6 to 67, or more than half, in 25 years.

At first glance, that looks as if the battle is nearly won, but the other side of the picture tells a different story. U. S. census figures show nine deaths every hour from tuberculosis. While such a condition prevails it is time for redoubled efforts, rather than any relaxation. The figures given above appear in a striking pamphlet issued by the Tuberculosis Society of the County of Monroe, entitled "A Five Year Program for the Medical Control of Tuberculosis in Rochester and Monroe County."

The pamphlet, packed with information, can be noticed only briefly here, but the kernel of it lies in its statement that 'more recently it has been recognized by physicians and health authorities that the tuberculosis problem lies solely in the early discovery of the disease.' It recommends therefore the survey of large groups such as pupils and teachers in schools and colleges, food handlers, industrial workers and city employees, to discover cases that may be spreading infection. Once a case is found all persons in contact with the victim, in home, school, shop, etc.,

should be examined. Then various methods of treatment are outlined.

The authors of the pamphlet, who modestly remain anonymous, summarize their findings as follows:

If we are to have an Ideal Program, organized medicine must show leadership.

1. With this leadership must go hand in hand, the help and guidance of the Health Bureau.
2. Cases must be uncovered by all the methods and technics at hand. Among the best methods for more rapid and early case-finding are the tuberculin skin test and the chest x-ray.

3. Contacts must be more generally examined and watched.
4. Reporting of diagnosed cases must be rigidly adhered to.
5. Improvements in technic of therapy must be periodically discussed.
6. Rehabilitation, follow-up, and after-care must be more effectively organized.
7. Reliable and necessary information regarding all phases of dealing with the disease must be prepared and distributed to those involved.

William Seaver Woods.

County Meetings Held

Speakers at the annual meeting of the Medical Society of the County of Franklin, Malone, October 30, were Drs. William V. Cone and David W. MacKenzie, Montreal, Que., on "Abscess of Brain—Diagnosis, Pathology and Treatment" and "The Prostate—Its Pathological Aspects and Newer Forms of Treatment," respectively, and Harold H. Berman, Ogdensburg, on "Psychoneurosis."—Dr. Louis C. Kress, Buffalo, gave a paper on "Five Year Cancer Cures" at a meeting of the Dutchess-Putnam Medical Society, November 8, in Poughkeepsie.—A symposium on neurology was presented by three Syracuse physicians before the Medical Society of Jefferson County, Watertown, November 9; Dr. Eugene N. Boudreau discussed pathology, Dr. Wardner D. Ayer, pathology, and Dr. Albert B. Siewers, clinical manifestations.

Health at Utica

Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended December 9, indicate that the highest mortality (20.2) appeared for Utica and that the rate for the group of cities as a whole was 12. The mortality rate for Utica for the corresponding week of 1932 was 11.7 and the rate for the group of cities, 12.3. The annual rate for the eighty-five cities was 10.9 for the forty-nine weeks of 1933, as against a rate of 11.1 for the corresponding period of last year.

University News

The University of Buffalo announces competition for its annual award of a gold medal to the author of a paper on an ophthalmologic or allied subject. Details may be obtained by writing to the dean of the medical depart-

ment or to Dr. Harold W. Cowper, 543 Franklin Street, Buffalo, chairman of the committee on award.

New Clinic for Occupational Disease

New York University and Bellevue Hospital Medical College has opened a special clinic for occupational diseases, with a laboratory equipped for the work. Cases of lead poisoning, silicosis, occupational dermatoses and benzene poisoning have already been handled in the clinic, which meets Wednesday afternoons. Physicians and industrial health workers have been invited to refer cases.

Landlords of apartment houses in San Francisco are offering free medical, surgical and hospital service to tenants who pay their rent in full on the date when due.

An interesting plan is being tried out in a Mormon settlement in Western Canada. The town has about 2,000 people, who have voted to pay the two local doctors \$25 a year for each family, and in return the doctors guarantee complete medical and surgical care, even including major operations. Each physician receives about \$3,750 a year under this plan, beside occasional fees for treating families who do not join. The doctors and townspeople thus are both relieved of worry over unpaid bills. How the scheme would work in a larger community is, of course, another question.

A medical writer in Kansas, disgusted with the medical ballyhoo he hears on his radio, remarks wearily that "the day may come, and soon we hope, when one can sit by his radio and get a genuine and continuous thrill of Wagnerian opera without being interrupted by a radio announcer who tells the audience of the air what it should take to make its bowels move."

Society News

New York Physicians' Mutual Aid Association

Announcement by Treasurer

In my official capacity as Treasurer of the New York Physicians' Mutual Aid Association, I am continually being asked how is the Association faring in these times of depression and what is the financial status of the medical profession in general. Of course, as we operate solely in New York State I am not in a position to know about any other territory. In this state, and I believe in the larger centers of population particularly, the medical profession is not very prosperous. Even those who have patients find very little cash coming in for services rendered. However, for centuries past, in sunshine and rain, in hard times and good, in times of pestilence and disaster, we have stood bravely by doing our duty towards that portion of the public that required our services. Let it be said to the credit of the medical profession that in these times of stress those of us who had and still have a bit, have not forgotten those who may have had once but have nothing now. Here and there among the doctors special funds have come into existence to help care for local needs among medical men, but none of these funds, so far as I know, has answered the roll call of "helping hands" to their fellow-members in distress as has this sixty-five-year-old Association. It is perfectly true that we have confined our relief work to our membership but that membership has always been open to those who wanted to come in when they were eligible—and that membership is still open to eligible non-members. Information may be obtained by writing or telephoning the Association, Atwater 9-4638 at the Academy of Medicine, 2 East 103 Street, New York City, room 552.

Sixty-five years is a long time for an Association to function and keep a clean record. This Association has done so without a break in the aims that its illustrious founders set for it in 1868. It has come through several periods of depression successfully, just as it is doing in this one. It is able to do this, of course, because it has in the past and is now receiving loyal support from its members, and new members are coming in steadily to fill the vacancies caused by death and otherwise. Likewise, with its officers and trustees serving, as always, without pay or other financial gain, office expenses are kept down to an irreducible minimum, without interfering with the proper running of the Association. In fact, the officers and trustees besides paying, just as do other members, fail to charge the Association for outlays made in its behalf by them at various times.

Many men who thought they were members of this Association just for the good work it was doing for others of the profession, have had occasion in the recent past and present to seek loans. Times have changed for many of us and the end is not yet. Therefore, membership in this Association is more valuable today than ever before. Men in the recent past who thought their savings and insurance were a-plenty for the future care of their families are very glad that today they have membership certificates in this Association tucked away.

The expense is small, the returns large and you will find yourself in company with the best in the profession of the State of New York.

To our members who might read this article, or even to non-members who feel generous, and who also may have friends who want to give to a worthy cause, I recommend our Benevolence Fund as a most worthy object for contributions, large or small. Loans are made without security, without publicity and, without reason, without interest for the duration of the loan. Of course, loans are restricted to members but our membership is several thousand and any eligible non-member is more than welcome to join in our great work.

To anyone wanting to add to his income, this Association offers an excellent opportunity in the way that does not belittle one's professional standing.

Here's hoping for better times in the near future, not only for the profession, but the public at large. In the meantime, we will be found continuing to do our part in the relief of the indigent sick, proud to be able to minister to their ills, even though without hope of reward, financial or otherwise.

Irving D. Steinhardt, M.D., Treasurer.

Note—It has come to our knowledge, and we have verified the information, that to date, the investments of the Association have been so managed that all dividends have been fully paid to date.—Editor.

Civil Works Administration

In the last issue of THE JOURNAL there appeared the Special Rules and Regulations governing skilled work projects for nurses and certain professional personnel engaged in Medical Relief.

Dr. James N. Vander Veer, Chairman of the Contact Committee, draws attention to the fact that since the C.W.A. is now in operation throughout the State, there should be less work on the part of the T.E.R.A. inasmuch as the male population and some of the female population of the State probably will be employed through the C.W.A. (Turn to page 33)

Medicolegal

An Ungrateful Patient

An excellent example of ingratitude on the part of a patient is found in a case decided during the last few weeks by an Appellate Court of one of the Western States.

A woman about sixty-five, who had suffered trouble from her appendix for nearly forty years, became acutely ill and consulted her physician. A specialist in abdominal surgery was called into consultation and an immediate operation was advised. The patient entered the hospital and all preparations were made for the operation, but just before it was scheduled she suddenly left the hospital against the doctor's advice, in an ambulance.

After several days at home the patient's condition finally became very critical and she agreed to undergo the operation. She was again rushed to the hospital and operated upon without further delay. Her condition before operation was extremely poor. Her appendix had apparently ruptured some time before, and pain was general throughout her entire abdomen which was distended. She showed marked dehydration and was extremely toxic. She was mentally dull. Her lips and fingernails were blue. The doctors felt that the chances to save her life were very slim, and they feared that she would die on the table.

The surgeon who had been consulted previously, operated with the family doctor acting as anesthetist. The operation revealed that the appendix had ruptured and peritonitis had set in. Concededly the operation was skillfully and satisfactorily performed. Her condition immediately after the operation was described by her physician as follows:

"When she returned from the surgery her condition was even more critical, owing to the necessary shock of an operative procedure. She returned to her room with cold extremities; blue cyanosed extremities; her heart beats were much more weakened than before; her pulse was very rapid, running from 140 to 150 at the heart, and at the pulse the circulation was so weak the patient would not come through to the pulse, the wrist, and it was possibly only about 30 or 40 beats each minute. The pinched and drawn toxic expression of the face was present, and all the tissues were dehydrated. In other words, she was suffering from the shock of an operation plus the most toxic type of absorption from the appendix that had been ruptured at least eight days."

The doctors were up against the problem of sustaining life, and promptly held a consultation. They concluded that a saline solu-

tion containing 10 percent glucose should be administered. The intravenous method of injection was ruled out, because of the patient's toxic condition. A hypodermoclysis of a 10 percent glucose solution was ordered and given subcutaneously in the patient's thighs by an interne at the hospital. The patient's life was saved and she regained her health, but she underwent a sloughing of tissues at the places where the injections had been made.

About a month later the woman, then appreciative of her indebtedness to the doctors, wrote to the operating surgeon in part as follows:

"Dear Loved Doctor W—I owe my life to your skill. This will remain with me to the end. * * * Affectionately and ever yours with deepest gratitude, N. C. C."

The patient's kindly attitude was short-lived, for sometime later she brought an action to recover damages for the sloughing against the doctors, the interne, a nurse and the hospital. The trial resulted in a dismissal as to all but the surgeon and the family physician, and she recovered a substantial verdict against them.

Upon the trial only one medical witness was produced on behalf of the plaintiff. This physician had practiced medicine for about ten years, but had never performed a single abdominal operation or treated a case comparable to that of the plaintiff. He had examined her some months after she left the hospital, and he testified to the presence of scars and a loss of tissue. He stated in answer to a hypothetical question, that these conditions were caused by "something wrong with your solution." He asserted that 5 percent was the highest safe glucose solution to be used subcutaneously, and that apparently well over 20 percent had been used. He further testified that no benefit could be expected to a person in extreme shock and dehydrated in giving that person more than 5 percent glucose under the skin, and also that there was nothing to prohibit giving such a person glucose in the veins.

The witnesses who testified on behalf of the defendants included certain eminent doctors of many years' experience, and their testimony was unanimously in support of the procedure followed. That the defendants acted in the case in an attempt to use their best judgment for the patient's welfare, seems clear from the following testimony which one of them gave:

"Q. Now, Doctor, at the time that you prescribed the 10 percent solution for the

hypodermoclysis, did you know at that time the possibility that it might cause sores? A. Yes.

"Q. And knowing that it might cause sores, why did you do it? A. We would much rather have a chance of having our patients live than have them die with clear legs.

"Q. In other words, it was a case of saving her life? A. It certainly was.

"Q. And before you actually did it did you take consultation with Dr. W? A. I did.

"Q. And did he share your view? A. He did.

"Q. If the situation had not been so critical, would you have used 10 percent? A. Probably not.

"Q. Probably not. But it was because of the crisis? A. That is right."

For the judgment in favor of the plaintiff an appeal was taken and the higher Court, in deciding that the record required a reversal and judgment in favor of the defendants, handed down an extremely well written opinion. In this opinion the Court said:

"The main question before us is whether the evidence was sufficient to sustain the verdict against the defendant doctors. Appellants contend it was not, and in our opinion this contention must be sustained. * * * There is no evidence showing that the diagnosis made by the attending physicians was not entirely correct. The paramount duty of the doctors under the circumstances was to endeavor to save the life of the patient. There is no evidence to challenge the judgment of the doctors in determining that an injection of a solution containing 10 percent glucose was essential to accomplish that purpose. There is no evidence to show that in the condition in which they found respondent a 10 percent solution could have been injected in the veins without defeating that purpose. In other words it does not appear that respondent's life could have been saved by any method of treatment other than the one prescribed by the defendant doctors. Under these circumstances, it certainly was not malpractice to save the patient's life, even though this was accomplished by the subcutaneous injection of a solution containing a higher percentage of glucose than is ordinarily injected and even though sloughing resulted at the points of injection."

The Court further said:

"We are concerned on this appeal only with a charge of unskillfulness on the part of the appellants in the selection of the method of treatment. It is a matter of common knowledge that such selection is a matter of judgment and opinion upon which the most skillful members of the medical pro-

fession will often honestly differ. It has therefore been stated that 'a physician is required to possess only ordinary skill in his profession, and to use his best judgment in the exercise of that skill, and if he complies with these requirements, he is not liable for the non-success of his treatment.'"

The Court ruled that if the testimony of Dr. H, the plaintiff's expert, could be given any consideration, it still should be considered as insufficient to make out a prima facie case of negligence against the defendants.

The Court said:

"In the opinion of several other medical experts whose testimony stands unimpeached, the method selected by appellants was the recognized and approved method of treatment for such condition. In other words, if Dr. H's opinion may be said to be in conflict with the opinions of the several medical experts called by appellants, the case presented was one showing that the medical experts were at variance in their opinions as to the method of treatment that should have been employed. Under the circumstances, we are of the opinion, that appellants could not be held liable if they acted within 'the reasonable limit of either opinion.' * * * To hold otherwise would mean that the medical profession would be confined in their selection of methods to the use of those methods, if any, which have the universal approval of all the members of the profession and that new or different methods, having the recognition and approval of a minority, including many of the most able practitioners could never be employed without the risk of a charge of malpractice resulting therefrom. The progress of the medical profession should not be obstructed by placing such an unreasonable limitation upon the selection of methods of treatment."

No reasonable person could dissent from the conclusion reached by the Appellate Court. The verdict of the jury, like so many jury verdicts, was a gross injustice, and the Appellate Court clearly did the right thing in correcting the injustice of the jury's verdict.

A specialist in ear, nose and throat work was consulted with respect to the condition of a nineteen-months'-old child. The doctor found the child had diseased tonsils and adenoids and suggested an operation. Under a general anaesthesia the doctor dissected out both tonsils and removed the adenoids with an adenotome. There was very little bleeding and this was controlled by packing. The child was returned from the operating room to bed, and about ten hours afterwards the gauze packing having been first removed from the child's throat, the child was taken to its home.

The next the doctor heard of the case was a few days later, when he was called to the home of the child. He found it to be suffering

from a temperature of 103. He made a careful examination of the throat and failed to find anything to cause the high temperature. Examination at that time showed that there was no gauze or any foreign substance in the throat. The doctor received word that another doctor had been called in and was looking after the child's fever, so did nothing further.

The doctor did not hear anything further in the matter for another month, when the parents brought the child to the doctor's office. Examination showed a swollen gland on the side of the neck and a slight infection of the left ear, so the doctor ordered cold compresses and argyrol dropped into the nostrils. For the ears he ordered a two percent solution of carbolic acid and glycerin.

Three days later the child was again brought to the doctor's office. The swollen gland had improved, but there was still some infection of the ear. Four days later the doctor observed that the child was apparently developing an abscess of the ear and he suggested that the child be brought back so that he might open the ear within forty-eight hours. However, the child was not brought back to this doctor thereafter, and he never saw the child again professionally. He heard indirectly that the abscess burst without operation and the child recovered with no difficulty.

Suit was brought against the doctor by a guardian ad litem who was appointed for the infant, the complaint charging the doctor with having negligently operated on the child and claiming damages as a result thereof. The case came up for trial before a judge sitting without a jury. The claim of the plaintiff was that the doctor had failed to remove a piece of gauze that he had inserted into the child's throat postoperative. The further claim was made that for ten days following the operation the child ran unusually high temperature, and on the tenth day in the presence of witnesses the gauze in question was coughed up. The doctor on the witness-stand denied that he had ever left any gauze in, although he admitted that he had used some gauze in the course of the operation all of which he had removed. The judge handed down a decision in favor of the defendant

doctor, exonerating him of the charge of malpractice.

Burn From Lamp Treatment

A physician who specialized in the treatment of nose, throat, eye and ear cases, in the course of his practice served on the eye and ear clinic of a certain hospital. A girl about twenty years of age came to the clinic for treatment, and the doctor examined her and found that she had enlarged glands on the left side of her throat. He placed her in a chair and adjusted a Kromayer quartz lamp so that the rays were concentrated on said gland. He turned on the electric current and gave instructions to his assistant, who was a practicing physician, to watch the patient and shut off the lamp at the end of ten minutes. The doctor then went to another part of the clinic and treated some other patient.

About twenty minutes later he returned to where he had left the first patient, and found that she was still sitting with the rays of the lamp concentrated on her neck. The doctor immediately shut off the lamp and examined her. He found the skin was somewhat red, dened at the point of exposure. The patient went home and returned two days later, at which time the doctor found a blister about the size of a pea had developed. He prescribed a certain salve and paste for the condition and told the patient to return for further examination, but he never saw her again professionally.

Sometime later a lawsuit was instituted charging the doctor with negligence in his treatment. The case came to trial before a judge and jury, and the plaintiff testified that she had been subjected to the rays of the lamp for a period of forty-five minutes, with a resultant blister. The defendant, however, and his witnesses were able to convince the court that the damages sustained by the plaintiff were not due to any negligence on the part of the defendant doctor. A motion to dismiss the complaint was granted at the close of all the testimony, the judge not permitting the jury to pass on the issues in the case.

Civil Works Administration

(Continued from page 29)

Several County Societies have already appointed representatives to pass on lists of physicians submitted to them as applicants for employment in "skilled work projects" as to their professional standing and economic status, in so far as it is related to eligi-

bility for participation in such projects.

The Erie County Society has already taken steps under the Act to provide fifty local physicians with paid work for the indigent by augmenting existing municipal services in the city of Buffalo.

Books Received

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

If I Have Children

By G. Francis Smith, M.R.C.S. 12mo. of 133 pages. New York, Oxford University Press, 1933. Cloth, \$1.75.

Food, Nutrition and Health

By E. V. McCollum, Ph.D. and J. E. Becker, M.A. Third Edition. 12mo. of 146 pages. Baltimore, E. V. McCollum & J. E. Becker, East End Station [c.1933.] Cloth, \$1.50.

Surgical Anatomy

By Grant Massie, M.D. Second Edition. Octavo of 458 pages, illustrated. Philadelphia, Lea & Febiger, 1933. Cloth, \$6.00.

A Study of Rural Public Health Service

For the Committee on Administrative Practice of the American Public Health Association by the Sub-Committee on Rural Health Work. Edited by Allen W. Freeman, M.D. Octavo of 236 pages. New York, The Commonwealth Fund, 1933. Cloth, \$2.50.

Record-Librarian's Manual

A Guide to Organizing, Classifying and Filing Clinical Records and Medical Literature. By Carl E. Black, M.D. Octavo of 154 pages. St. Paul, Minn., Bruce Publishing Company, 1933. Cloth, \$2.00.

The 1933 Year Book of Radiology.

Diagnosis, edited by Charles A. Waters, M.D. Therapeutics, edited by Ira I. Kaplan, M.D. Octavo of 804 pages, illustrated. Chicago, The Year Book Publishers. [c.1933.]

A Text-Book of Medicine

Edited by Russell L. Cecil, M.D. Third Edition. Octavo of 1664 pages. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$9.00.

Applied Pharmacology

By A. J. Clark, M.D. Fifth Edition. Octavo of 632 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., 1933. Cloth, \$5.00.

Diet and Dental Health

By Milton T. Hanke. Octavo of 236 pages, illustrated. Chicago, University of Chicago Press, [c.1933.] Cloth, \$4.00.

Surgical Clinics of North America

Vol. 13, No. 5, October, 1933. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues.) Cloth, \$16.00; Paper \$12.00.

A Manual of Diseases of the Nose, Throat and Ear

By E. B. Gleason, M.D. Seventh Edition. 12mo. of 651 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$4.50.

Starling's Principles of Human Physiology

Sixth Edition, edited by C. Lovatt Evans, D.Sc. Octavo of 1122 pages, illustrated. Phila., Lea & Febiger, 1933. Cloth \$8.75.

Behind the Doctor

By Logan Clendening, M.D. Octavo of 458 pp. illus. N. Y., A. A. Knopf, 1933. Cloth, \$3.75.

Pathogenic Microorganisms

A Practical Manual for Students, Physicians and Health Officers. By William Hallock Park, M.D., and Anna Wessels Williams, M.D. Tenth Edition. Octavo of 867 pp. illus. Phila. Lea & Febiger, [c. 1932.] Cloth, \$7.00.

Infections of the Hand

A Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand and Forearm. By Allen B. Kanavel, M.D. Sixth Edition. Octavo of 552 pp. illus. Phila. Lea & Febiger, 1933. Cloth, \$6.

Industrial Health Service

By Leverett D. Bristol, M.D. 12mo. of 170 pp. Phila., Lea & Febiger, 1933. Cloth, \$2.00.

Maternal Mortality in New York City

A Study of all Puerperal Deaths, 1930-1932. By the New York Academy of Medicine Committee on Public Health Relations. Ransom S. Hooker, M.D., Director of Study. Octavo of 290 pages. New York, The Commonwealth Fund, 1933. Cloth, \$2.00.

The Practical Medicine Series

Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1933. Chicago, The Year Book Publishers [c.1933.] The 1933 Year Book of General Medicine, edited by George F. Dick, M.D., and others. 12mo. of 831 pages, illustrated. Cloth, \$3.00.

Metabolic Diseases and Their Treatment

By Dr. Erich Grafe. Octavo of 551 pages, illus. Phila., Leo & Febiger, 1933. Cloth, \$6.50.

The Medical Clinics of North America

Volume 17, No. 3, November, 1933 (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues.) Cloth, \$16.00 net; paper, \$12.00 net.

International Clinics

A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 4, 43rd Series, 1933. Edited by Louis Hamman, M.D. Octavo of 317 pages. Philadelphia, J. B. Lippincott Company, 1933. Cloth, \$3.00.

Bacteriology for Medical Students and Practitioners

By A. D. Gardner, 16mo. of 276 pp. N. Y., Oxford University Press, 1933. Cloth \$2.25.

Mayou's Diseases of the Eye

Fourth Edition, revised and largely rewritten by Frederick Ridley, B.Sc., and Arnold Sorsby, M.D. 12mo. of 249 pages, illustrated. N. Y. Oxford Uni. Press, 1933, Cloth, \$2.25.

Books Reviewed

The Motion Picture as a Professional Instrument

By William F. Kruse. Quarto of 28 mimeographed pages. Chicago, Bell & Howell Company, [1933].

This is a pamphlet of twenty-seven pages giving an outline of practically every phase of taking medical movies. It will be of special value to the increasing number of physicians who are using the 16 mm. film. It describes many pieces of accessory apparatus and suggests new methods in lighting, focussing, exposures, editing and all other procedures in taking medical movies.

F. OVERTON.

The Health School on Wheels

By J. Mace Andress, Ph.D., and I. J. Goldberger, M.D. 12mo. of 399 pages, illustrated. New York, Ginn & Company [c. 1933]. Cloth, 76c.

This is one of a series of books prepared by the same authors which deal primarily with health instruction to children. The book follows the general principal of the other books in this series and is well adapted and very interesting.

A book of this type cannot fail to interest not only the younger children, but indeed the older children, as well as the teachers themselves.

Practically all phases of public health are gone into and this book can well be recommended as a project in the classroom where hygiene and kindred subjects are taught.

S. ZWERLING.

Fetal, Newborn, and Maternal Morbidity and Mortality

Report of the Subcommittee on Factors and Causes of Fetal, Newborn, and Maternal Morbidity and Mortality. Hugo Ehrenfest, M.D., Chairman White House Conference on Child Health and Protection. Octavo of 486 pages, illustrated. New York, D. Appleton-Century Company, Inc., [c. 1933]. Cloth, \$3.00.

This report, prepared by Ehrenfest as chairman of a very representative subcommittee on Factors and Causes of Fetal, Newborn, and Maternal Morbidity and Mortality of the Committee on Prenatal and Maternal Care of the White House Conference on Child Health and Protection, is excellent. Like the volume on Obstetric Education it should be carefully read by every obstetrician. Though it perhaps contains nothing new; much information has been gathered together in one place. The material is well arranged and presented for the purpose of stimulating interest in an important problem. If every man doing obstetrics should read it, the problem would be solved.

CHARLES A. GORDON.

Chronic Illness in New York City

By Mary C. Jarrett. In two volumes. Octavo of 545 pages. New York. Published for The Welfare Council of New York City by the Columbia University Press, 1933. Cloth, \$5.00.

This study of chronic illness in New York City "was intended primarily to open up the subject in such a way that thinking, both for immediate planning and for further study of this large question, could be organized around certain central themes." It is one of the studies of the Research Bureau of the Welfare Council and is published for the Welfare Council by the Columbia University Press, in two volumes. A thorough study has been made of chronic illness as presented in New York City in individuals and groups of all ages, and useful suggestions have been made for the prevention of these conditions which make a large number of individuals dependent upon their own relatives, or upon the community. This study, while freely advising the physician concerning the entire care of these individuals, especially after these individuals have discharged themselves from the care of the physician and will not follow medical advice, concerns itself more with the sociological aspect of the problem than with the medical, except in prevention. The question of financial loss to the community, of the family responsibility of these individuals, and the duty of the community in caring for these cripples is presented. The study is thorough, complete, accurate, well written and will repay a careful review of these volumes.

HENRY MONROE MOSES.

Orthopedic Surgery

By Walter Merced, M. D. Octavo of 695 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$10.50.

This textbook on Orthopedic Surgery is well put together and well illustrated. X-ray pictures do not predominate and illustrations of pathological specimens and mechanical diagrams are many.

The purpose of the book is to produce a moderate sized textbook that is sufficient for the student and yet not a complete treatise on the subject. The book well fills this purpose and is a valuable addition to the textbooks on this subject.

Dr. Mercer is a general surgeon who specializes in and teaches orthopedic surgery in the Edinburgh University. As a result, the book gives much of the attitude of a general surgeon but is, however, purely orthopedic.

The foreword is by Professor John Fraser who in turn, has a similar background to Dr. Mercer.

JA. C. RUSHMORE.

Filterable Virus Diseases in Man

By Joseph Fine, M.D., 12mo. of 144 pages. Baltimore, William Wood & Company, 1932. Cloth, \$2.25.

The author has written an interesting and useful book which gives in a compact way a description and classification of virus diseases, particularly from the pathological and bacteriological standpoint. The references given from the literature bring the subject matter quite up to date, and make the book of value to the student and practitioner of medicine affording, as it does, a résumé, in brief but logical sequence, of the present status of our knowledge of virus diseases, at least as concerns, their causation, transmission and the pathological changes they induce.

JOSEPH C. REGAN.

The Operative Story of Cleft Palate

By George M. Dorrance, M.D. Octavo of 564 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$6.50.

It is really surprising to see the amount of interesting material that can be embodied in a book of this size.

Apparently no operation, whether sensible or ludicrous has escaped the author's attention. They are all given space with comment on them all.

Complete descriptions of the modernly recognized operations of choice could not very well be undertaken in a work of this size, but in the author's conclusions the reader gets a very good idea of the best features of the recognized procedures. The good and bad features are pointed out with reason for the same.

The author's own operation "The Push Back Operation," as he calls it, is very well described and illustrated and is based on the applied anatomy of the region and physiology of the Palate.

The book is well worth reading. The extensive Bibliography is a work of reference in itself.

S. H. DECOSTE.

Gastric Anacidity. Its Relations to Disease

By Arthur L. Bloomfield, M.D. and W. Scott Pollard, M.D. Octavo of 188 pages. New York, The Macmillan Company, 1933. Cloth, \$2.50.

In this book, the authors have collected all the data widely scattered through the literature on the subject of Gastric Anacidity. The book is replete with the work done on the subject from the days of Beaumont to the present.

These authors have contributed a great deal to our understanding of this important subject and in a concise, interesting manner have presented the question to the profession.

The importance of gastric anacidity has become well recognized in recent years and in this monograph, the authors have given the profession a most practical and useful review.

IRVING GRAY, M.D.

Outline of the Cranial Nerves

By John Favill, M.D., 12 mo. of 112 pages, illustrated. Chicago, The University of Chicago Press [c. 1933]. Cloth, \$1.50.

The author has compiled a very admirable compend of 112 pages with several illustrative diagrams. Each of the cranial nerves has been considered under five headings: anatomy, function, tests, pathology and localization. The sections dealing with tests and their significance should be especially interesting and instructive to the novice in neurology. As stated by the author in his foreword, nothing new has been presented but old facts have been collected from many sources and regrouped. This should make a very handy book not only for the undergraduate medical student for whom it was intended, but also for the general practitioner as a quick reference source.

JEFFERSON BROWDER.

The Thyroid Gland. Its Chemistry and Physiology

By Charles R. Harington, Ph.D. Octavo of 222 pages, illustrated. New York & London, Oxford University Press, 1933. Cloth, \$4.50.

In this monograph, the author has given us a rather complete survey of the chemistry of the thyroid gland. Beginning with the early, crude notions of thyroid function, he outlines the progress made in the chemistry of the gland with especial reference to the role of iodine and its probable significance in the etiology, physiology and pathology of goitre. The early investigations are passed over quickly. However, beginning with Baumann's discovery of iodothyronin, the author details a complete story of the important discoveries in the chemistry of the thyroid and its various iodine-containing compounds. A large part of the book is concerned with the preparation and chemistry of thyroxine, in which subject the author is an outstanding authority.

With regard to etiology, the author concludes that the fundamental cause of goitre is inadequacy of the supply of iodine to the thyroid. His reasoning appears rather sound and convincing with respect to simple colloid goitre; it seems to us less convincing in the matter of exophthalmic goitre and toxic adenoma.

In addition to rather complete data regarding the purely chemical aspects, there are interesting discussions of the physiology of the thyroid, cretinism, the interrelationship of the thyroid with other endocrine organs, etc. These discussions concern themselves largely with such properties which illuminate or are themselves clarified by chemical relationships.

The work is thoroughly scientific and technical and will appeal more to the biochemist and physiologist than to the practitioner of medicine. The book should be especially helpful to anyone wishing to study the matter of thyroid diseases from an investigative point of view.

ARTHUR GOETSCH.

To Be or Not to Be A Study of Suicide

By Louis I Dublin, Ph D, and Bessie Bunzel, M A Octavo of 443 pages, New York, Harrison Smith and Robert Haas, 1933 Cloth, \$3 50

Why should one seek to kill himself? This is the absorbing and vital question dealt with in this new book by Dublin—"To Be or Not To Be" The many and varied motives leading to such an act are discussed in detail A few of the conclusions which Dublin has drawn from his extensive investigation are

1 That the Germans show by far the high est suicidal tendency, the negroes and the Italians, the least

2 That the United States is not classed among the nations showing the greatest suicidal frequency

3 That the rural suicide rate is considerably lower than the urban rate

4 That one will go to great lengths to kill himself in a particular manner offering him the greatest psychic satisfaction, and will equally shun some other, possibly easier, method

5 That economic depression per se will not lead to suicide

6 That traditions and customs play distinct roles in controlling the frequency of such an erratic act The power of the Catholic Church more than of any other religious affiliation is instrumental in curbing suicide

These and many other facts presented in an authoritative manner make this an outstanding reference book on this subject

The author concludes with the statement that "there is no simple solution to the suicide problem and no unfailing way to keep a despondent person from killing himself"

EMANUEL KRIMSKY

Massage and Remedial Exercises in Medical and Surgical Conditions

By Noel M Tidy Octavo of 429 pages, illustrated Baltimore, William Wood & Company, 1933 Cloth, \$5 25

This book is unusual in the field of Massage It brings under one cover general consideration, varieties, causes, general symptoms, complications and principles of treatment of fractures, dislocations, sprains, diseases of joints and the nervous system, deformities and constitutional diseases

Its description of fractures and dislocations is decidedly brief but presents a systematic outline to guide the attending surgeon and masseur in such a way that unnecessary trauma or harm might not undo the preliminary treatment of the surgeon Then, too, it serves as an excellent guide to those doing emergency nursing in hospitals and industrial plants as to how fractures, dislocations and sprains might be correctly immobilized until the attending surgeon institutes his treatment

Well illustrated plates showing applications of splints and bandages include every type of fracture and dislocation

A well written chapter on deformities of the spine illustrates correction of faulty posture and gives the necessary exercises for their cure

This book is well worth an inspection and might serve as a handy reference for the prescribing in after care of all joint and bone conditions

JOSEPH I NEVINS

Modern Aspects of Gastro-Enterology

By M A Arzfa, M R C P (London) Octavo of 374 pages, illustrated Baltimore, William Wood & Company, 1933 Cloth, \$8 25

In a book profusely and well illustrated, the author has presented his views on modern aspects of Gastro Enterology in a simple and interesting fashion

The subject matter is written in the interest of the general practitioner and clinician

After discussing the lesions of the stomach and intestines including an interesting chapter on the simulation of gastrointestinal diseases, the author concludes his book with a chapter on practical dietetics which makes the book complete in its purpose

IRVING GRAY

Collected Papers of the Mayo Clinic and the Mayo Foundation

Edited by Mrs Maud H Mellish Wilson and Richard M Hewitt, M D Vol 24, 1932 Octavo of 1205 pages, illustrated Philadelphia, W B Saunders, 1933 Cloth, \$11 50

The 1932 Collected Papers of the Mayo Clinic maintain the high excellence of the previous volumes which have been issued during the past two decades Fine judgment has been used in the selection of the papers which are here reprinted in full, only 99 out of a total of 484 papers written in 1932 are thus presented

An excellent departure is the omission of bibliographies It strikes the reviewer that if this were routinely done in the preparation of books which are for the general practitioner, diagnostician and general surgeon, a considerable expense might be avoided in the publication and the value of the book, would not suffer.

About 175 authors have contributed, and the contents are too numerous for even brief mention of outstanding papers Noteworthy articles are to be found under diseases of the alimentary tract, ductless glands, blood diseases, respiratory diseases, nervous system and radiology

M A RABINOWITZ

Great Men of Science A History of Scientific Progress

By Philipp Lenard Translated from the second German edition by Dr H Stafford Hatfield Octavo of 389 pages, illustrated New York, The Macmillan Company, 1933 Cloth, \$3 00

Doctor Lenard, a Nobel prize winner and

formerly director of the Radiological Institute at the University of Heidelberg has fathomed the past 2500 years and has unearthed 64 outstanding personalities who have, in his opinion, made the most substantial contributions to scientific progress from the standpoint of physics. Of these, only 16 or 25% are of possible Aryan extraction. This is mentioned not to minimize the accomplishments of the Germans but to emphasize that the truly great man is humble enough to bury his bigotry.

The author has failed to include any of the contemporaries in his consideration for, he feels, they are not as great as the "giants" of the past. While this book is intended for the layman it is hardly conceivable that he will appreciate its true flavor unless he be versed in astronomy and optics and dynamics and other branches of the physical sciences. It will win its immediate appeal to a select group of scientists. Its material, however, should attract a DeKruif to write a more elementary edition for the layman.

EMANUEL KRIMSKY.

Migraine. Diagnosis and Treatment

By Ray M. Balyeat, M.D. Octavo of 242 pages, illustrated. J. B. Lippincott Company, [c. 1933]. Cloth, \$3.00.

That the dietary control of migraine is more successful than for any other chronic ailment is the contention of this author. Migraine, we are told is a hereditary, allergic symptom complex closely related to and often associated with asthma, hay fever, and urticaria. Genetic case histories are cited for purposes of illustration.

With certain statements contrary to established opinion many will disagree. The author maintains that migraine does not disappear with advancing age; also, that there are 5,000,000 migraine sufferers in this country. One may question whether he has not also included other forms of headache in his conception of migraine.

In spite of these discrepancies this book has certain commendable features. Its theoretical and clinical dissertations including descriptive case records are presented in scholarly fashion. The chapter on therapy is ambiguous because the author has included about every form of treatment which one might try without evaluating them critically.

It is to be hoped that others will be as successful with diet as Balyeat claims. At any rate, he will inspire optimism in his readers by constantly stressing the importance of allergic investigation.

EMANUEL KRIMSKY.

Diseases of the Nervous System

By W. Russell Brain, M.D. Octavo of 899 pages illustrated. New York & London, Oxford University Press, 1933. Cloth, \$8.75.

An amazingly complete textbook of diseases of the nervous system. It is strictly up-to-date.

For this quality alone, it deserves the highest praise. This volume is a gem to possess. To read it, is a pleasure. To review it, is a privilege.

Russell Brain—how appropriate a name for a specialist in nervous diseases—has the rare faculty of making his subject live, imparting feeling to what is commonly a drab portrayal. He possesses a mastery of the English language, and a captivating charm of expression. Throughout there is a definiteness, sureness and clarity of description sharply delineating each clinical picture, avoiding confusion in a manner possible only to one of vast clinical experience and profound knowledge of his subject.

The arrangement of material in any textbook on nervous diseases is always in conformity with the author's pet ideas. Admittedly there is difficulty in knowing exactly where to place some matter into the general scheme of things. In this book however there is a smoothness and orderliness of arrangement because of which one subject seemingly flows freely into the following.

Throughout the basic anatomic and physiologic aspects are given vigorous emphasis, for in no specialty is the thorough understanding of these elementary studies so unquestionably necessary as in diseases of the central nervous system.

The subject matter is discussed under nineteen separate chapter headings with many subdivisions. It is essentially a treatise on organic disease, barely twenty-five pages being devoted to the discussion of the neuroses. The chapter on "Diseases of the Nervous System in Relation to Life Insurance" is a novel and valuable feature. To the insurance examiner it should prove to be indispensable. This chapter is typical of the book as a whole in being brief, clear and practical.

Of special appeal to the reviewer was the very sensible but rarely used method adopted in grouping the references in a body at the end of the book. The references are carefully detailed under each subject.

This volume is of such a high grade of all-round excellence that when future textbooks in this special field are contemplated, this book by Russell Brain should prove to be the recognized standard of measurement.

HAROLD R. MERWARTH.

Frontiers of Medicine

By Morris Fishbein, M.D. 12 mo. of 207 pages. Baltimore, Williams & Wilkins Company, 1933. Cloth, \$1.00. (Century of Progress Series).

The "Frontiers of Medicine," from the pen of no less a gentleman than the Editor of the "Journal of the American Medical Association," gives a very entertaining account of some of the great medical geniuses, from the days of pre-historic times to the present day. After a short review of what he styles "In the

Beginning," touching the pre-hippocratic period, the author discusses the period of Hippocrates and Galen, the medieval ages, the revolt against Galen (Paracelsus), the rise of anatomy (Vesalius), the rise of physiology (Harvey), the evolution of clinical medicine (Sydenham), the birth of Bacteriology (Pasteur), and the "introduction of mechanical accessories which have prolonged and extended the human senses and thereby improved greatly man's ability to study and treat disease." Dr. Fishbein then goes into the modern period. He stresses the change which is inevitably taking place in the practice of medicine today, owing to rapid advances in our knowledge of the human body and its functions, the progress in organic chemistry, the wonderful technical apparatus at our disposal and, "last but not least," the growing disposition of the State to take cognizance of the needs and rights of the people in matters pertaining to their health and happiness. The book is a multum in parvo, which gives a broad sweep of the great ideals in medicine from the dawn of history to our own times. It can be carried in one's pocket and should be read and re-read. Though brief, one can find much to read "between the lines" for thought and serious action.

J. M. VAN COTT.

International Clinics

A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 3, 43rd Series, 1933. Edited by Louis Hamman, M.D. Octavo of 316 pages, illustrated, Philadelphia, J. B. Lippincott Company, 1933. Cloth \$3.00.

The noteworthy contributions of this volume are the articles on diseases of the parathyroid gland which include the diagnosis of parathyroid over function by Wilder, hyper-

parathyroid underd tetany of the new-

discusses hypothyroidism associated with pituitary disease. Morris lays great stress on the thyroid toxicoses which are masked by normal and subnormal basal metabolic rates.

This volume has an excellent résumé of present day knowledge on infectious mononucleosis (glandular fever). The articles on diabetes by Strouse and spondylolisthesis by Kleinberg are noteworthy.

There is an occasional article which might have been omitted. Greater discrimination in the selection of papers by the editor would prove a distinct advantage to the popularity of these volumes.

M. A. RABINOWITZ.

Proceedings of the First International Congress On Mental Hygiene

Vols. 1 & 2. Edited by Frankwood E. Williams, M.D., Octavo of 1643 pages. Illustrated,

New York, The International Committee for Mental Hygiene, Inc., 1933.

The present record of the justly memorable congress in May, 1930, is formidable evidence of how the mental hygiene movement has made the world psychiatric conscious. It would be impossible adequately to review the material without writing one's own history of the development. Let it be said at the outset that Dr. Williams accomplished an admirable work in editing which matches the imposing efforts of the organization.

Together with the proceedings of the other congresses which took place simultaneously in Washington, D. C., these volumes offer a source book of the numerous fields into which psychiatric study has branched in our time. Aside from the purely organization papers, the work is excellently balanced by many authoritative articles from the realms of child guidance, hospital treatment, psychoanalysis, social work, penology, the family, psychology and others. When one adds the fruitful discussions which are appended, one gains a world-wide panorama of the work done in this department of medicine and its sociological environs. There has arisen some criticism of the mental hygiene movement as propaganda, but, in the face of this array of material, there can be little doubt that through its efforts our former concepts of a purely material progress in society have been beneficially altered. We have come upon an era of studying humans and their human relationships and there can be little question that a development in this direction is an adequate and fruitful field for psychiatry, whatever its various subspecialties may eventually call themselves. The psychiatrist as well as the practitioner or layman will find these proceedings an accessible method for orientation in the whole field of psychiatric advance.

SAM PARKER.

Senile Cataract

Methods of Operating. Second Edition. By W. A. Fisher, M.D. 12mo. of 267 pages, illustrated. Chicago, Chicago Eye, Ear, Nose and Throat College, [c. 1933].

After a period of ten years the second edition of this little volume comes from the press materially improved. The illustrations, as in the original, are diagrammatic in type, but nevertheless exceptionally clear and understandable. The contributors are of world-wide renown, various chapters being from the pens of Fuchs, Barraquer, Holland, Wright, Van Lint and Nugent. As would be expected from the above names, the intracapsular method of extraction is strongly emphasized. The text is well arranged and the descriptions of technique, etc., are clear. The book deals primarily with operative procedures which have come to be accepted as standards, but there are sections devoted to the management of complications and modifications of technique to meet special requirements.

Altogether the work is quite unique and has a definite place in ophthalmic literature. It could be supplemented by more elaborate chapters on methods of extraction in which the capsule is opened. The chemistry and biological phases of cataract development could be thoroughly discussed, particularly as a great mass of material has lately become available in the literature. The book is not only useful to the student but also to the established practitioner who needs occasionally to review the technique.

JOHN N. EVANS.

New and Non Official Remedies, 1933

Containing descriptions of articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1933. 12mo. of 498 pages. Chicago, American Medical Association, 1933. Cloth, \$1.50.

The annual editions of this volume contain all that the busy physician needs to know concerning the newer preparations which he is daily importuned by the detail men of the pharmaceutical manufacturers to use. The remedies listed and described here have been examined and found acceptable by the Council on Pharmacy and Chemistry, the deliberative body charged by the American Medical Association with the performance of this service for the practitioner who has not the time or means to make the determinations for himself. Among the new preparations admitted during the past year are: Trichlorethylene-Calco, an inhalation anesthetic proposed especially for use in trigeminal neuralgia; Nostal, an additional barbituric acid compound; Decholin and Decholin Sodium, bile salt preparations for use in functional insufficiency of the liver, the sodium salt being suitable for intravenous use when necessary; Biliposol, Bismo-Cymol, and Iodobismitol, bismuth compounds for use in obtaining the systemic effects of bismuth, especially in syphilis; Triphal, a gold salt proposed for use in the treatment of lupus erythematosus; a number of improved liver preparations for use in the treatment of pernicious anemia; two halibut liver oil preparations of high vitamin A and vitamin D content; and Pentnucleotide, the sodium salts of the pentose nucleotides derived from the ribonucleic acid of yeast, proposed for use in infectious conditions accompanied by a leukopenia or neutropenia.

The book contains general articles, descriptive of the classification under which the various drugs are listed. According to the preface, more or less thorough-going revisions have been made of the articles: Arsenic Compounds; Dyes, Iodin Compounds; Liver and Stomach Preparations; Radium and Radium Salts and Silver Preparations.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry

Of the American Medical Association for 1932, with comments which have appeared in the Journal. 12mo. of 104 pages. Chicago, American Medical Assoc. 1933. Cloth, \$1.00.

This volume contains the reports on products considered and rejected by the Council during the past year. Among the reports of special interest are: Amertan, an unoriginal mixture of tannic acid and merthiolate in a water soluble jelly, marketed under a proprietary, uninforming name; Antiopin, a mixture of indefinite composition offered under a nondescriptive, therapeutically suggestive name and marketed in a way that may foster the drug habit; Eubetin, another insulin substitute for oral administration marketed under a proprietary uninforming name with unwarranted claims; Ferro-Copral, a mixture of saccharinated ferric oxide, manganese citrate and copper proteinate proposed for use in the treatment of pernicious anemia and marketed under a proprietary name with unwarranted therapeutic claims; Hepatex P.A.F., a liver preparation proposed for intravenous use and marketed under a proprietary and insufficiently descriptive name with no satisfactory evidence of the safety of its recommended intravenous use; Bi-So-Dol, an unscientific "alkalinizing" mixture offered under an uninforming proprietary name with exaggerated and unwarranted claims of therapeutic usefulness; Gan-Aiden, consisting mainly of the well known ethyl amino-benzoate (benzocaine), a preparation of undeclared composition marketed under a noninforming proprietary name; Myodin, Subidin, and Sanguiodin, unscientific preparations of iodine marketed with unwarranted claims and indefinite, incorrect statements of composition, under proprietary uninforming names and Tonikum-Roche (Now Elixir Arsysten Compositum-Roche), a "shot-gun" proprietary "tonic" marketed with misleading therapeutic claims.

Besides the reports on rejected articles, the volume contains "Preliminary" and "Special" reports of exceptional timeliness and value: The preliminary report on Thorotrast, a colloidal thorium dioxide preparation proposed for use in retrograde pyelography and for roentgen visualization of the liver and spleen by intravenous administration, is an excellent example of this class of reports. The articles on Nirvanol and Triethanolamine are also interesting and effective preliminary reports. Among the "special" reports those on Sulpharsphenamine and Mercurochrome are outstanding. Each report definitively clears up the present status of the drug concerned, the former, on the basis of a questionnaire circulated among leading syphilologists, and the latter on the basis of independent bacteriologic investigation, done by consultants of the Council.

Analysis of 376 Consecutive Oxygen-treated Cases From a Study Made at the Presbyterian Hospital, New York, from 1929 to 1932

by

ALVAN L. BARACH, M.D.*Assistant Attending Physician, Presbyterian Hospital,
New York City*

Read at the annual meeting of the Medical Society of the State of New York at New York City April 4, 1933

IN 1929, we reported 100 cases of pneumonia in an oxygen tent or oxygen chamber treated during the years 1926 to 1928¹. Most of the cases were on ward care at the Presbyterian Hospital, although a moderate number were patients treated in private practice. In each instance, the patients were generally selected for treatment because a decided turn for the worse had taken place, and consequently comprised examples of severe pneumonia, rather than mild or abortive forms of the disease. The mortality rate of the 100 cases was 45 per cent, which appeared to be a low figure when compared with the usual mortality in this type of clinical material selected. Additional comparison was made with the results of Stadie² who reported a mortality of 93 per cent in a group of cyanotic lobar and postinfluenzal bronchopneumonia not treated with oxygen, and with that of Binger³ who reported a mortality of 56 per cent in a series partly treated with oxygen. By these comparisons the inference was strengthened that effective oxygen therapy favorably modified the course of the disease in some instances. However, the complexity of the factors known to modify pneumonia mortality were too great to permit statistical proof that the mortality rate in severe cyanotic pneumonia was lowered, although individual instances of recovery were suggestive of such a conclusion. The experience of Boothby and Haines⁴ and that of Judd⁵ and his collaborators in postoperative bronchopneumonia appeared to indicate even more decisively the favorable results of oxygen therapy in pneumonia oc-

curring as a complication of surgical procedures.

The present report concerns 376 consecutive cases treated with oxygen therapy at the Presbyterian Hospital from 1929 to 1932. No patient who received oxygen during this period was excluded, so that the results are those obtained from routine hospital management of a variety of diseases. It should be mentioned that the employment of oxygen therapy was not controlled by a changing interne service but was under the direction of a department that assumed the responsibility for providing 40, 50 or 60 per cent oxygen when it was ordered by the hospital staff. The oxygen apparatus, including every tent, chamber and catheter in use, was inspected one to three times daily by one of the two technicians who were especially trained for this work. Thus, while the clinical material was mostly selected by the hospital staff because of therapeutic indications and only in certain instances for the purpose of research, the provision of effective oxygen therapy was carefully controlled. The importance of this factor cannot easily be overestimated when it is realized how frequently the management of oxygen therapy by internes results in complete failure to test the oxygen concentration the patient is supposed to receive.

The cases have been divided into those treated on the medical and those on the surgical wards, because of the critical difference due to an operation as a factor in the latter group. There were 271 cases treated with oxygen on the medical wards during this period, which have been analyzed in the following tables according to diagnosis, type of therapy employed and duration of treatment. In Table I, it is observed that of 124 cases of pneumonia, including lobar and bronchopneumonia, there were 58 deaths, or 46.7 per cent. This figure is quite similar to the mortality of 45 per cent in the series previously reported¹.

Table 1.—MORTALITY OF OXYGEN-TREATED CASES ON MEDICAL WARDS

Including Lobar and Bronchopneumonia

Diagnosis	Number of cases	Number of deaths	Mortality, per cent	Remarks
Pneumonia	124	58	46.7	Includes heart failure due to rheumatic, degenerative or coronary artery disease.
Cardiac insufficiency...	109	67	61.4	Includes acute coronary thrombosis only.
Coronary thrombosis..	11	7	63.6	Includes tuberculosis, asthma, fibrosis of lung, etc.
Miscellaneous	27	15	55.5	47 additional cases of medical group had less than 24 hours' treatment.
Total	271	150	55.3	

The second group, cardiac insufficiency, comprises patients who showed symptoms of heart failure due to previous rheumatic disease or present rheumatic fever, degenerative forms of heart disease (ordinarily described as chronic myocarditis) and cases of myocardial failure dependent upon coronary arterio-sclerosis. Of the 109 cases treated, there were 67 deaths, or a mortality of 61.4 per cent. In collaboration with Richards⁶, we have made a special study of the effects of oxygen therapy in various forms of congestive heart failure, which has been responsible for the relatively high use of oxygen in this group. A further report⁷ is in preparation indicating that marked benefit frequently occurs in patients who have degenerative forms of heart disease whereas those whose heart failure is due to rheumatic damage manifest slight or only temporary improvement. The third group consists of 11 cases of coronary thrombosis, of whom 7 died, giving a mortality of 63.6 per cent. Levy and the author⁸ reported instances of acute coronary thrombosis in which oxygen therapy appeared to sustain life until the heart established a mechanism of adapting itself to the abrupt shock and anoxemia caused by the vascular closure. Although the mortality rate indicates that 7 of 11 cases died, the gravity of the results in these cases is well known. In some of the patients who recovered, the influence of oxygen therapy seemed to confirm the previous conclusion of its decisive helpfulness in certain instances.

Additional evidence of the value of effective oxygen therapy in coronary occlusion is found in similar studies by Rizer⁹, Ulrich¹⁰ and Kilgore¹¹. The relief of chest pain both in acute thrombosis and sclerosis of the coronary artery by oxygen indicates that it fulfils a functional need. Better results will perhaps be obtained when more cases of acute coronary thrombosis

are treated with continuous administration of 50 to 60 per cent oxygen in a modern tent or a chamber, even in the absence of dyspnea or cyanosis, for the first 4 to 5 days after the onset. In these cases, the oxygen concentration should be gradually lowered to that in the atmosphere over a period of twenty-four hours.

The effects of oxygen therapy in congestive heart failure have also been studied by Hamburger, Katz, and Cohen¹². Further discussion of the indications and value of its use in chronic cardiac insufficiency will be the subject of the paper already referred to.

The last group of miscellaneous cases does not justify further analysis; it included cases of pulmonary tuberculosis, asthma, fibrosis of the lung, suppurative pleurisy, and other conditions. There were 27 cases, of whom 15 died, a mortality of 55.5 per cent. Of the total of 271 cases there were 150 deaths, or a mortality of 55.3 per cent. The effect of the duration of treatment will be mentioned later in more detail, but it is desirable to indicate at this point that 47 cases of this group had oxygen treatment less than twenty-four hours.

On the surgical wards, there were 42 cases of pneumonia, of whom 22 died, a mortality of 52.3 per cent. This group comprises all cases who were definitely diagnosed as bronchopneumonia. It includes patients who also suffered from sepsis as well as other complications. The second group of miscellaneous conditions includes sepsis, shock, embolism, neoplasm, paralytic ileus, cardiac failure, and any condition for which oxygen was used at some time during the illness. Of 63 cases, 48 died—a mortality of 76.2 per cent. The relatively higher mortality on the surgical service is probably related to the presence of terminal complications other than purely respiratory disturbances. The total mortality of 105 cases treated with oxygen on the surgical wards was 69.5 per cent.

Table 2.—MORTALITY OF OXYGEN-TREATED CASES ON SURGICAL WARDS
Classified According to Diagnosis

Diagnosis	Number of cases	Number of deaths	Mortality per cent	Remarks
Pneumonia	42	22	52.3	Includes postoperative bronchopneumonia with or without complications
Miscellaneous	63	48	76.2	Includes deaths from sepsis, shock, embolism, neoplasm, and cardiac failure.
Total	105	73	69.5	53 cases of surgical group had less than 24 hours' treatment.

During the period of this study the total number of hospital deaths on the two floors from which the surgical data were obtained was 310. Of these, 73, or 23.5 per cent were treated with oxygen. On the medical wards, there were 668 deaths during this period, of whom 150, or 22.3 per cent were treated with oxygen. In other words, approximately one case out of four that die, either on the medical or surgical wards, receives oxygen treatment. This fact indirectly represents the acknowledged severity of the cases who obtain oxygen therapy. In view of this circumstance, the combined total mortality of the medical and surgical services, 223 deaths of a total of 376 cases, or 59.3 per cent, is not a high figure.*

In Table 3 the mortality of the oxygen-treated cases on the medical wards has been analyzed according to the duration of treatment. In the previous series of 100 patients, the fatal cases had an average duration of oxygen treatment of 2.5 days, whereas the recovered cases had an average duration of treatment of 6.0 days. In the present report, the cases have been divided into those who had oxygen treatment 1 day or a fraction of a day (from 1 to 24 hours), those who received oxygen treatment 2 to 3 days, and those who were treated 4 days or more. The combined mortality for nasal-catheter, oxygen-tent and oxygen-chamber cases on the medical side who received oxygen treatment for a period of 24 hours or less, was 87.2 per cent; those

treated 2 to 3 days had a mortality of 62.3 per cent; the group treated 4 days or more had a mortality of 39.3 per cent.

The mortality rate of the cases treated one day or less on the surgical wards was 74.4 per cent, those treated 2 to 3 days, 70.0 per cent, and cases treated 4 days or more, 54.5 per cent. If a selection is made of only oxygen-tent and oxygen-chamber cases treated on the medical wards, the contrast is greater. The mortality rate of patients treated one day or a fraction of a day was 92.8 per cent, whereas those treated 4 days or more had a mortality of 30.5 per cent.

These figures are presented for their factual interest rather than with the attempt to prove statistically that long-continued administration of oxygen tends to lower the mortality rate. They confirm an obvious rational assumption that a practice of withholding oxygen therapy until cardiac or respiratory failure is imminent is not apt to produce beneficial results. A report based upon cases that received oxygen less than 24 hours, therefore, could not be used as a criterion of the effectiveness of oxygen therapy. An additional reason for mentioning the lower mortality in the cases treated over a long period of time is found in a certain confusion that exists concerning the possibility of undesirable habituation to high oxygen atmospheres.

In discussion of oxygen therapy, a statement is at times heard that patients may be

Table 3.—MORTALITY OF OXYGEN-TREATED CASES ON MEDICAL WARDS
Classified According to Duration of Treatment

	1 Day or less			2 to 3 Days			4 Days or more		
	Num-ber of cases	Num-ber of deaths	Mortality, per cent	Num-ber of cases	Num-ber of deaths	Mortality per cent	Num-ber of cases	Num-ber of deaths	Mortality per cent
Nasal catheter.....	33	28	84.8	51	31	60.8	101	44	43.5
Oxygen tent.....	9	8	88.8	9	6	66.6	19	7	36.8
Oxygen room.....	5	5	100	9	6	66.6	35	10	28.5
Total	47	41	87.2	69	43	62.3	155	61	39.3

* The total number of deaths on both medical and surgical wards was 978. The total number of patients who received oxygen treatment, including fatal and recovered cases, was 376.

Table 4.—MORTALITY OF OXYGEN-TREATED CASES ON MEDICAL WARDS

Classified According to Type of Oxygen Therapy

Type of oxygen therapy	Number of cases	Number of deaths	Mortality, per cent	Remarks
Nasal catheter	185	105	56.7	Nasal catheter sole method used.
Oxygen tent	37	21	56.7	Includes oxygen tent, plus cases transferred to tent after previous catheter treatment.
Oxygen chamber	49	21	42.8	Includes oxygen chamber as sole method, plus cases previously treated with catheter or tent.
Total	271	150	55.3	47 cases of medical group had less than 24 hours' treatment.

come used to the inhalation of high percentages of oxygen and subsequently become unable to survive on lower concentrations. To some extent this impression has been founded on results I have published in which symptoms of collapse have taken place when patients who were acutely ill were withdrawn from a high oxygen environment. In these instances, however, the mechanism of the collapse of the patient was dependent, as originally stated, on the fact that the disease process in the lungs had not cleared up or had advanced. When the patient is kept in an oxygen environment until the pathological state responsible for anoxemia has disappeared, he may be taken out of the tent or chamber without risk. This is unqualifiedly true for acute cases, as I have repeatedly withdrawn such patients, who have been in a tent or chamber for two or three weeks, from the inhalation of high mixtures without change in their condition, granted the pathological process had cleared. In cases of chronic anoxemia, such as occurs in chronic cardiac and chronic pulmonary conditions, the problem of therapy is more complicated¹³. The inhalation of 50 per cent oxygen may be necessary for three weeks to three months before compensation is regained. In these instances, a gradual lowering of the oxygen concentration is generally advisable.*

However, even in the chronic cases, the use of oxygen *in no instance* renders him less able to continue without oxygen; either he recovers so that he may continue without oxygen or he relapses into the condition present before oxygen was begun. In these cases, a gradual lowering of the oxygen concentration is advisable because the degree of cardiac and pulmonary improvement is more limited than in acute disease in which a normal lung was present previous to the illness.

The type of oxygen therapy employed has

been analyzed in relation to mortality. In Table IV, the mortality of 185 cases treated with the nasal catheter was 56.7 per cent. An identical mortality was present in the cases treated with the oxygen tent. However, the cases grouped under the heading of nasal catheter received oxygen *only* by nasal catheter. When their condition became worse, they were frequently transferred to an oxygen tent. The oxygen-tent group contains, therefore, not only cases treated with the oxygen tent but also those who were previously treated with the catheter and who failed to respond to the catheter. The nasal-catheter mortality in the surgical cases was 67.1 per cent, and the oxygen-tent mortality as high as 84.0 per cent.

The same circumstance, namely, that the patients who did not respond to nasal catheter treatment or those who were getting worse with it, applies to the cases treated in the oxygen room. In addition, this group includes cases that were transferred from the tent to the chamber for the same reason. However, in both the medical and the surgical cases, the mortality of the cases treated in the oxygen chamber was 42.8 per cent, considerably lower than in the other types of treatment. The factors involved in an estimation of the effectiveness and value of the various methods of treatment are too complex to render them susceptible to statistical argument. The results are recorded in percentages merely to complete the study. One is permitted, nevertheless, certain deductions from an inspection of the results as well as from clinical familiarity with the material.

We introduced into the hospital the use of the nasal catheter with a calibrated gage, for the treatment of the milder forms of anoxemia, because it was inexpensive and convenient¹⁴. Provided that the patient breathes through his nose, the administration of 2 to 4 liters of oxygen per minute results in approximately 30 to 35 per cent oxygen in the inspired air. As will be seen from an inspection of the above tables, the largest percentage of

¹³ Barach, A. L., and Richards, D. W.: *Am. Rev. Tub.* 26:241, 1932; Richards, D. W., and Barach, A. L.: *Am. Rev. Tub.* 26:253, 1932

* A more complete discussion of the management of the cases will appear in a forthcoming paper by Richards and Barach on the use of oxygen in chronic cardiac and pulmonary conditions.

¹⁴ Barach, A. L.: *J. A. M. A.* 93:1550, 1929.

cases were treated with this method. A still larger number of cases were begun on the catheter, which was discontinued because it failed to relieve the anoxic state. In an earlier study¹³ the author compared the effectiveness of the catheter with that of the tent and chamber by measuring the increment of the arterial oxygen concentration, and found the catheter to be definitely less effective. The catheter, however, was continued as the routine method largely because of the ease of application and because the tent and the chamber at that time were more difficult to manage than they are at present. The experience which we have had in the past three years indicated that the nasal catheter is frequently inadequate to meet the burden of anoxemia in the severely ill patient, and that, furthermore, much valuable time is often lost in trying the nasal catheter first. Patients have been observed who have used the nasal catheter for several days with persisting cyanosis or tachycardia and who were transferred to the tent or chamber only when more serious symptoms of collapse were impending. To that extent nasal-catheter administration may be at times responsible for plunging the therapeutic use of oxygen back to the state where it was a decade ago, namely, instituting oxygen therapy when the patient is approaching the moribund state.

We have unwittingly collaborated in this unfortunate circumstance by speaking of the nasal administration of oxygen as a method of mild effectiveness. It has, however, a field of usefulness for *mild* cases, particularly in the absence of a good tent, adequately managed, or a chamber. There is also a clear indication for the use of the nasal catheter in chronic cardiac and pulmonary cases during the transition from the tent or chamber to room air; for these patients a gradual reduction of oxygen concentration may be desired. In the studies of relief of the symptoms of congestive heart failure by Richards and myself,¹⁴ we have rarely not observed a recovery of compensation by the initial use of the catheter, but we have frequently seen the maintenance of improvement as a result of catheter administration following a previous period of treatment in high oxygen.*

The results mentioned above seem to be in favor of oxygen chamber treatment, for even with the inclusion of the severe cases that did not respond to the catheter or tent, the mortality is noticeably less. The point must be additionally mentioned because it coincides with Boothby's¹⁵ observation that a fall in temperature due to high oxygen inhalation is more constant in the chamber than it is in the tent, even though theoretically the oxygen con-

centration is the same in each. Perhaps the fact that the concentration of oxygen is much more constant in the chamber than in the tent is involved. Feeding and nursing the patient in a tent does produce more variations in oxygen concentration than occur in the chamber, in which the oxygen concentration may be kept relatively constant. There is little doubt in the mind of the author that the chamber treatment is superior both in comfort and effectiveness to any other, but the recent improvements in the oxygen tent make it possible to use it much more frequently and effectively than in the past.

The modern tent should be noiseless, capable of a wide range of ventilation without modifying the oxygen concentration, capacious and so freely supplied with windows as to be light inside. Tents which are not ventilated are worse than useless, for reasons which are sufficiently obvious if the comfort of the patient is considered essential. The tents should be tested for maintainance of 40 to 50 per cent oxygen, as is desired, three times daily by a trained technician, who also should regulate the ventilation flow to correspond with the desired temperature and humidity. The carbon dioxide concentration should be tested routinely. However, in our experience, concentrations greater than 2 per cent carbon dioxide within the tent do not occur except possibly for the briefest time, and in no instance with conceivable harm to the patient, even though soda-lime is not used. (For post-operative treatment of patients with hyperthyroidism, the use of soda-lime is advisable, as Boothby¹⁵ suggests.) An initial inflow of 15 liters per minute for 20 minutes, followed by a continuous inflow of 7 to 8 liters per minute, is the standard procedure in the wards of the hospital, modified as the individual circumstances require. With oxygen and ice, a cost of \$6 per day compares favorably with a cost of \$3 to \$4 per day for nasal-catheter administration. The most important factor in making possible the substitution of the tent for the catheter is that the modern tent can be used on ward patients without the expense of a special night and day nurse, which was necessary with the original tent. For these reasons of a technical nature and because severe anoxemia is not adequately relieved by the nasal catheter, our opinion is that the tent or chamber should be employed without previous recourse to the catheter in severely ill patients wherever it is practicable. Testing the oxygen concentration within the tent is *essential*, as there is no other way of being certain that the patient is receiving the concentration of oxygen his condition requires. There are times when an oxygen concentration of 60 to 70 per cent is necessary for periods of hours, and other times when 40 per cent is adequate. The determination of the *dosage*, that is, the oxygen concentration desirable for the particular patient, depends on experience in treating anoxic patients,

* We have not yet employed insufflation into the oral pharynx with the high flows of 7 to 8 liters per minute recommended by Wineland and Waters. (Arch. of Surgery, 22:67, 1931.)

¹³ Barach, A. L.: Arch. Int. Med. 37:186, 1926.

¹⁴ Boothby, W. M.: J. A. M. A. 99:2026, 1932.

and this experience obviously can never be gained when a tent is applied routinely without actual accurate determination of the concentration of oxygen employed.

Summary

A report is made of 376 consecutive oxygen-treated cases from the medical and surgical wards of the Presbyterian Hospital, New York, for the years 1929 to 1932.

The mortality of the entire series was 59.3 per cent. The mortality for the medical cases was 55.3 per cent, for the surgical cases, 69.5 per cent. The cases were analyzed according to: (1) diagnosis, (2) duration of treatment, and (3) type of method employed. There were 124 cases of pneumonia treated on the medical wards with a mortality of 46.7 per cent. In a previous report of 100 cyanotic pneumonia patients, the mortality rate was 45 per cent. The complexity of the factors involved in pneumonia mortality are such as to prohibit deriving a conclusion on a statistical basis that oxygen therapy lowers the mortality rate in pneumonia, although a comparison of the results in other series, and observation of relief of symptoms in individual patients, are suggestive of such an opinion. That the respiratory function, in respect to the absorption of oxygen, is sustained by effective oxygen therapy in severely anoxic cases of pneumonia seems apparent from the reported clinical and physiological studies of individual patients. Some of these patients ultimately recover. It is from this kind of observation rather than from statistical argument that we have obtained the belief that oxygen therapy has a favorable effect on pneumonia mortality.

The influence of duration of treatment and the type of method employed are discussed in the text. Administration through the nasal catheter, although a method with mild effectiveness under certain conditions, may be responsible for the prevention of adequate oxygen therapy because of its employment in severely ill patients. Patients who might be relieved of anoxemia by the use of 50 to 60 per cent oxygen, or even 70 per cent oxygen for brief periods, in the tent or the chamber, at times progress to the point of collapse under the administration of oxygen through the catheter, and may then be incapable of relief even by the transfer to a higher oxygen environment. The use of the tent or the chamber for many cases now treated by the catheter seems advisable. The careful testing of the actual concentration of oxygen breathed by the patient is *essential* in the employment of the tent or chamber.

The use of oxygen therapy in various forms of cardiac insufficiency is discussed in the text. Studies by Richards and the author have shown that congestive heart failures secondary to degenerative forms of heart disease respond favorably to oxygen therapy, whereas heart failures due to rheumatic etiology show only slight or temporary improvement.

Additional experience by Levy and the author^{*} in the treatment of acute coronary thrombosis indicates that the inhalation of 50 to 60 per cent oxygen for the first four or five days may tide the patient over the period of shock and anoxemia induced by the vascular closure. In many cases it is indicated at the onset of the occlusion, even in the absence of cyanosis.

^{*} To be published.

THIS AND THAT

An experiment well worth watching is being tried in California. In the City of San Fernando, in Los Angeles county, the curative clinic, where the indigent sick were treated free by physicians who gave their services gratuitously, has been discontinued, and the indigent patients are now referred to the physicians' offices and treated there. The physician receives a nominal fee from the county of 50c per patient treated, for the use of his personal equipment and office facilities. The new plan is said to be regarded favorably so far both by the physicians and the county authorities. Fewer patients apply for treatment, and the cost to the county is something like \$200 less per month. The plan has been in operation about four or five months.

* * *

Hospital authorities whose institutions have lost money by treating automobile accident victims who have never paid will be interested to learn that in Ohio a new law will make be-

tween \$250,000 and \$300,000 available during the year to reimburse hospitals for expenses incurred in the care of indigent persons injured in automobile accidents. Only hospitals "organized and operated not for profit" will benefit. If the patient later becomes able to pay, the hospital is expected to collect his hospital bill and repay the state fund.

* * *

A medical correspondent reported from Nairobi, East Africa, to the London papers, that the brains of 100 adult natives of Kenya weighed, on an average, 150 grammes less than the European. On reading this item, a waggish English physician wrote in to remark that this amount "represents approximately the disparity in weight between the average for male and female brains of English adults," and he added: "Chivalry forbids further comment." What happened to him after his women patients saw his letter has not been reported.

Symposium on Hoarseness

HELD AT ANNUAL MEETING OF THE MEDICAL SOCIETY OF
THE STATE OF NEW YORK IN NEW YORK CITY, APRIL 5, 1933

Etiology, Symptoms, and Diagnosis of the Inflammatory Type of Hoarseness

by

WILLIAM ANDREW KRIEGER, M.D., F.A.C.S.

Poughkeepsie

HOARSENESS being a symptom of so many different conditions and not a disease entity, we must first consider its pathological mechanism. In order to produce a clear vocal tone, the vocal cords must (1) approximate, (2) assume the proper tension, and (3) vibrate according to the tone desired. Anything interfering with one or all of these components will alter the clarity of tone of the particular voice and produce what is most commonly called hoarseness.

As to the etiology of the inflammatory type of hoarseness, I believe, we must first consider those which come under the classification of emergency, (1) *diphtheria*, *acute edema* and *Vincent's infection*. I wish to emphasize the importance of Vincent's infection, which can easily be confused clinically with diphtheria, not only in adults but in children. When culturing a patient for Diphtheria, it is a simple procedure to take a smear for Vincent's. In many instances, much time can be saved in treatment and, I believe, lives saved. I know of a number of cases diagnosed clinically as Diphtheria with negative cultures for Klebs Loeffler Bacilli, but smears showed true Vincent's infection and recovery resulted from the administration of Arsenic.

(2) *Chemicals* must also be considered. One case in particular came to my attention recently. A boy eleven years old swallowed a piece of dry ice, CO₂, and almost immediately he had slight dyspnea and hoarseness. I saw him about one half hour after the incident, at which time he had a slight edema of the epiglottis and moderate edema of the orifice of the esophagus, fortunately it was not severe enough to call for any emergency treatment. I mention this case because dry ice is coming more into general use and we are apt to see more of these conditions particularly in children. The caustics in the Lyes must be mentioned here as chemical causes of hoarseness.

(3) As to the *allergic type*, I will cite the following case. Patient E. C., age 52 years, was vaccinated on July 6, 1932. Two days later noticed a rash over the entire body, which she described as "hives", this rash

remained constant until November 1932 and gradually diminished until January 1933, when it entirely disappeared. On August 4th, 1932, she was awoken with a choking sensation, hoarseness and loss of voice. The hoarseness varying with loss of voice continued for about ten hours. These attacks recurred from weekly to ten day intervals until November 1932 when the attacks occurred about a month apart, the last being January 1st, 1933. I saw her on the morning of August 5th, 1932, the right vocal cord was moderately edematous and showed extravasation of fresh blood. I saw her again after the second attack, at this time the right cord was normal and the left cord showed the same condition present as in the right cord at the previous examination. I assume this to be Allergic. I would be pleased to have any other explanation brought out in the discussion.

Another case, I wish to mention Patient M. C. A., who gives his history as follows: "Age 69 years. Developed Malarial fever in 1898 while serving as assistant surgeon with the United States military forces in Honolulu. The recovery from this was slow and was followed by catarrhal condition of the nose and Eustachian tubes which caused about 75% deafness in the right ear, and deafness to a lesser extent in the left ear. There was considerable hoarseness which was persistent and at times amounted to almost complete aphonia. For the relief of these conditions I was treated for a number of years by an eminent specialist in New York City. Both middle turbinate bones were removed and uvula excised. The progress of the deafness was arrested, the hoarseness was partially relieved while under treatment, but returned promptly when treatment was discontinued and the hoarseness continued for more than three decades. During the late years, 1920-1930, a very annoying, persistent, dry, hacking cough was present which was more pronounced at night, and interfered with rest, sleep, and for which the usual treatment was of no, or of little, avail. The hoarseness continued and was greatly aggravated by any effort of sustained speech. My condition was such that I was compelled

to give up practically all social life, and I was greatly handicapped in my professional work, especially when serving as medical witness in the Courts since much of the time it was quite impossible to speak loud enough to be heard by a jury. Having almost completely given up hope of any relief I had given up treatment for several years. The condition, however, grew worse during the winter of 1930-1931. Then I again took up treatment and some of the acute symptoms were promptly relieved. Headaches and the annoying sense of congestion of the sinuses disappeared; soon I noted less fatigue when speaking and less hoarseness. The condition has so far cleared up that I have no cough, the voice is clear and full, and I am able to carry on sustained conversation without fatigue or developing any hoarseness."

I first saw this patient on January 24th, 1931. The ears showed no perforations or discharge. Large cryptic tonsils. Septum quite straight. Anterior end of each middle turbinate had been removed. Turbinates were congested. There was muco-pus in ethmoid and sphenoid areas. Frontals were clear and antra hazy on transillumination. The larynx showed extremely edematous cords, with no loss of approximation or motion but considerable infiltration. The voice was very hoarse and an almost incessant cough was present. Blood Wassermann was negative. Allergic skin tests were negative. Under treatment, the right cord cleared quite promptly but it was almost a year and a half before the left cord entirely cleared. I last saw him on February 28th, 1933, at which time there was no edema

of either cord but a very slight amount of thickening present in each. The nasal condition is almost entirely cleared. I assume this case to be one of sensitivity due to absorption from the chronic ethmoid infection. I will be pleased for any enlightenment on this case.

Time will not permit going into the more common types, such as the Exanthemata, Acute infections, Irritation from post-nasal drainage, Foreign bodies, Injuries, Overstrain of voice, Myogenic and Neurogenic (1) central and (2) peripheral.

Syphilis, Tuberculosis and Neoplasm only require respectful mention as they will be considered in papers following in this symposium.

In the inflammatory type of hoarseness, the approximation of the cords is only slightly interfered with but the tension is very much impaired, varying with the severity of the condition present while the vibration varies directly with the tension.

As hoarseness is in itself only a symptom, and many times the only symptom complained of, it should be taken as the key to a complete investigation in order to arrive at the correct diagnosis.

Diagnosis should be made by direct or indirect inspection of the larynx or both; bacteriology; culture and smear; complete physical examination, including neurological, complete blood count and chemistry, blood and spinal fluid Wassermann, Tuberculin, Esophagoscopy, Bronchoscopy and Biopsy. Any or all should be carried out according to the requirements of the individual case.

103 HOOKER AVE.

Neurological Aspects of Hoarseness

by

E. D. FRIEDMAN, M.D.

New York City

Neuroanatomical Considerations

THE motor fibers of the vagus and glossopharyngeal nerves arise from the nucleus ambiguus which lies ventral to the vestibular nucleus and dorsal to the olive. These motor fibers supply the constrictors of the pharynx and the soft palate; the intrinsic muscles of the larynx are supplied by the recurrent laryngeal which leaves the vagus within the chest, winding around the aorta on the left and the subclavian artery on the right.

At the base of the skull the vagus lies dorsal to the ninth nerve, ventral to the eleventh nerve and the jugular vein, and lateral to the hypoglossus. Beyond this point it passes through the ganglion nodosum and then proceeds downward between the internal carotid and the internal jugular vein, lateral to the sympathetic.

Symptomatology

Disturbances in phonation manifest themselves by either hoarseness or complete loss of voice. The function of the vocal cords may, however, be seriously impaired without leading to changes in the voice. Hence the necessity for laryngoscopic examination. Difficulties in phonation may be the result of inflammatory changes of the mucous membrane or the deeper tissues, or may be due to paralysis of the muscles. The dilatation of the glottis, in inspiration, is accomplished by the crico-arytenoids.

The recurrent laryngeal nerve which supplies the intrinsic muscles of the larynx including the abductors and adductors of the vocal cords, may be damaged within the thorax, the nerve on the left being subject to compression by aortic aneurysm or other mediastinal tumor. Paralysis of this nerve has occurred from the pressure of a dilated

left auricle in cases of mitral stenosis. In such cases, bronchoscopic examination has revealed indentation of the bronchus on the left. In such instances of left recurrens palsy, the left vocal cord is paralyzed, being semi-abducted in the cadaveric position. The cord is immobile in inspiration and phonation. The intact cord attempts to pass over to the diseased side in phonation so that the voice is not entirely lost.

The left recurrent laryngeal is more frequently affected, owing to its longer course. In the early stages, the affected vocal cord lies in the midline because the abductor muscle is always paralyzed first (Semon-Rosenbach law). We find here a phenomenon frequently observed in the pathology of the nervous system, namely, that an injury to a nerve does not necessarily affect all its fibers equally. Semon and Horsley found that after the death of an animal, electrical irritability ceased first in the abductors. Donaldson and Hooper came to similar conclusions. Frankel and Gad found that refrigeration of the nerve first interferes with abductor function. Risien Russell thought that the fibers of the abductors of the larynx form a separate bundle in the recurrent laryngeal. Grabower found a poor nerve supply to the posticus. Onodi demonstrated that in horses, the fiber bundles for respiration and phonation are distinct. Sahli believed that the musculature of the adductors is considerably greater than that of the abductors; hence their greater resistance. Grabower and Kuttner maintained that the Semon-Rosenbach law holds for nuclear as well as peripheral lesions. The adductors are more important in phonation, coughing and straining. With increasing lesion of the nerve, the adductors also suffer and the cord then assumes the cadaveric position.

In the early stages of recurrens lesion, the voice is scarcely altered since the cords will meet in the midline during phonation; but when one vocal cord is completely paralyzed, the voice becomes hoarse or whispering and a strong cough is no longer possible because of the patient's inability to close the glottis and raise the intrabronchial pressure adequately. The involved vocal cord is also immobile in inspiration and only the normal cord goes into abduction.

In cases of aortic aneurysm, the cervical sympathetic may also be paralyzed with the recurrent laryngeal, as its fibers form a ring around the aorta. Lesions of this sympathetic plexus may give rise to a Horner syndrome (myosis, enophthalmos, pseudoptosis).

On the right side, the recurrent laryngeal winds around the subclavian artery. It is therefore less apt to be injured by tumors within the chest. The most common causes of paralysis of the right recurrent laryngeal are cancer of the esophagus, thickening of the pleura over the apex of the right lung and aneurysm of either the innominate or subclavian artery.

Both recurrent laryngeal nerves run upward on either side between the trachea and the esophagus and may be damaged in their course by stab wounds, the pressure of enlarged glands or operations upon the thyroid. Carcinoma of the thyroid is especially prone to implicate the nerve.

Bilateral recurrens paralysis may be produced by tumors of the esophagus and mediastinum, bulbar paralysis, tabes, multiple sclerosis, encephalitis, cerebral syphilis, polynuritis, diphtheria, ptomaine poisoning, influenza and lead poisoning. During the early stages, there may be attacks of laryngeal spasm owing to paralysis of abductors. In deep inspiration, the cords are drawn together causing stridor. There may also be an adductor contractive aggravating the difficulty. In later stages when the adductors are also paralytic, breathing is much easier but the voice is gone, the patient is unable to cough. There may be inspiratory stridor due to passive ballooning of the paralyzed cords.

In the first stages, laryngoscopic examination shows that the cords, on phonation, are close to the midline due to paralysis of the posterior crico-arytenoids. In the later stages, the cords are in the cadaveric position, midway between phonation and quiet inspiration and there is the risk of inhalation pneumonia.

The treatment includes that of the underlying general condition and avoidance of exercise. The prognosis in bilateral abductor paralysis is very grave. If acute dyspnea occurs, tracheotomy must be done to save life. This phenomenon may occur in tabes, general paresis, lead poisoning and diphtheria.

Lesions at the base of the skull (caries or malignancy) may give rise to typical syndromes. The syndrome of Vernet includes nasal regurgitation of fluids due to paralysis of the palate, dysphagia of solids due to paralysis of the pharynx, and hoarseness due to paralysis of the larynx. The syndrome of the retroparotid space includes, in addition to the above, atrophy and weakness of the sternomastoid and upper part of trapezius, atrophy and fibrillation of half of the tongue, and the syndrome of Horner (due to implication of the cervical sympathetic). We recall an instance of primary carcinoma of the tonsil on the left which was followed by the syndrome of the retroparotid space. In this case, in addition to the laryngeal palsy, there was unilateral paralysis of the palate, nasal voice, and occasional regurgitation of liquids. On inspiration, the palate hung lower on the affected side; on phonation, the raphé was drawn over to the sound side (phenomène de Rideau) and the arch of the palate was higher on the sound side.

The ninth, tenth and eleventh are usually injured together in lesions near the jugular foramen. These may be due to extradural abscess or basilar meningitis of luetic or other origin.

Lesions in the brain stem, such as bulbar

palsy, amyotrophic lateral sclerosis, multiple sclerosis, tabes, tumors of the pons and medulla, aneurysm of the basilar or vertebral artery and occlusion of the posterior inferior cerebellar artery may also lead to paralysis of the recurrens. The symptoms of occlusion of the posterior inferior cerebellar artery are rather characteristic. They include homolateral ataxia, homolateral anesthesia of the fifth nerve with loss of the corneal reflex, disturbances in pain and temperature sense on the opposite side of the body, paralysis of the homolateral vocal cord and palate, and usually, a Horner syndrome. At times one finds only implication of the fifth nerve and a laryngeal palsy. The syndrome of Avellis includes paralysis of the vocal cord and palate on one side and loss of pain and temperature sense on the opposite side of the body. The syndrome of Tapia, which occasionally follows injury, includes paralysis of the tongue and vocal cord on the side of the lesion.

Functional aphonia is most frequently met with in young women. It is usually associated with some emotional trauma. There is almost always a background of neurasthenia or psychasthenia.

The symptoms usually come on suddenly after extreme shock. The patient finds the voice gone or reduced to a whisper. There is no cough. Frequently one elicits a history of previous episodes of aphonia which passed off. In such instances, examination of the larynx shows that the cords are either not adducted at all or approach toward the midline, but the glottis is never completely closed. On coughing, the cords come close together so that the cough is not hollow or bulbar and during respiration, the movements are quite normal. The diagnosis is made on the history, the sudden onset and the absence of other causes for aphonia. The fact, too, that the act of coughing is not interfered with is significant. The absence of abductor paresis also indicates the functional nature of the syndrome. In the majority of cases the symptom complex disappears spontaneously.

Since the voice is intimately related with our affective life, hysterical aphonia is one of the commonest forms of functional paralysis. The aphonia is usually absolute. There may be an accompanying anesthesia of the pharynx. One of Oppenheim's cases of hysterical aphonia, when the moon came into her room, suddenly began to declaim a poem by Goethe; by the time she reached the third line of the poem, she lost her voice again. These hysterical aphonias are apt to recur.

Hysterical aphonia may also be the result of suggestion. I recall a private in whom aphonia developed as a result of a command of a superior officer to "shut up."

The treatment consists of psychotherapeutic suggestion and mental catharsis. In the early cases of hysterical aphonia, the simple passage of a laryngeal mirror or a sound may restore the voice. At times, faradic electricity

and respiratory gymnastics have also proved effective. In one stubborn case cited by Oppenheim, the voice returned in a patient as a result of a small incision made in the arm without induction of anesthesia. The patient fainted and when she came to, her voice had returned.

Occasionally we find disturbances in phonation in lesions of the precentral gyrus. There is a center for the adductors in the motor cortex and probably also one for the abductors. The presence of the former is suggested by the cry of the epileptic and the subsequent cyanosis due to spasm of the glottis. The existence of such a center is also borne out by the experimental induction of barking which I was able to accomplish in the dog through stimulation of the cortex low down in the motor zone. I have recently observed a case of pseudobulbar palsy on the basis of multiple vascular lesions in a chronic cardiac. This patient presented the emotional instability characteristic of this syndrome together with anarthria and impairment of the function of the adductors.

Diagnostic Considerations

In all progressive organic lesions of the centers and trunks of the motor laryngeal nerves, the fibers supplying the abductors of the vocal cords become involved much earlier than the adductors.

When the paralysis is confined to the adductors of the vocal cords, it is almost invariably bilateral and is due to functional disturbances in the central nervous system. The organic lesions produce either respiratory difficulty alone, or both respiratory and phonatory difficulties. A partial paralysis of phonation has been observed in multiple sclerosis and bulbar paralysis. Lead poisoning has been known to produce paralysis of the abductors as well as unilateral complete recurrens palsy.

In progressive bulbar palsy, phonation and respiration are found disturbed. In the later stages of the disease, the voice becomes monotonous and feeble. Hoarseness may supervene and go on to complete aphonia. The cough is weak and hollow. Laryngoscopic examination in the beginning of bulbar palsies may show relatively little. Later on we find paresis of the adductors, with insufficient closure of the vocal cords so that phonation is difficult. There are also other signs.

Tumors at the base of the skull or enlarged glands at the jugular fossa may damage the vagoglossopharyngeal nerves, producing unilateral paralysis of the palate and the vocal cord; lesions of the recurrent laryngeal will affect the vocal cord alone. If, therefore, paralysis of the palate accompanies paralysis of the vocal cord, it is useless to look for the lesion within the thorax. The source of the difficulty must be searched for at the base of the skull or in the brain stem.

Indications for Thyrotomy and Laryngectomy in Carcinoma of the Larynx

by
CHARLES J. IMPERATORI, M.D.

New York City

IT was in 1833, (1) just one hundred years ago, that Browers devised the operation of laryngofissure, or now generally known as thyrotomy, for the removal of polypi from the larynx.

In 1844, (1) Ehrmann removed a carcinoma of the larynx by this method and eleven years later, Gordon Buck (1) of New York, reported a successful operative result. His patient lived ten months after the operation.

Following this, there appeared in the literature, the results of about two hundred operations done by this method. Most of these patients died within two years following the operation, and in 1881, Cerny (1) and Yontis inferred that these operators should have removed the larynx in its entirety in order to obtain a cure.

The operation for the total removal of the larynx was first done in Edinburgh by Watson (2) in 1866.

Bilroth (3), assisted by Cerny, performed the first laryngectomy for carcinoma on December 31, 1873.

The operation for total extirpation of the larynx has been done for the past seventy-five years, but with more or less high mortality.

Until recent years, this high operative and postoperative mortality has continued. In 1922 Tapia (4) and MacKenty, (5) each reported a series of over one hundred operations, with an operative mortality of 5% and 4%, respectively.

Gluck and Soerensen have operated over one thousand patients, with increasingly good results and lowered operative mortality.

Sir Felix Semon contended that if an early diagnosis could be made, thyrotomy would suffice.

Henry Butlin agreed with Semon and some very good results were obtained. However, it became apparent to Butlin that in order to get no recurrence, the lesion in the larynx must be a small one and a diagnosis of its presence made early. This condition obtains today. There are certain lesions that, even though they are observed and diagnosed early,

are of such malignancy that the mere operation of splitting the larynx, excising the growth and surrounding tissue—"an oasis of carcinoma surrounded by a desert of healthy tissue"—does not suffice for a permanent cure.

Attempts at classification of the growths according to location have helped in determining the type of operation that should be done.

However, what we are most concerned about is whether or not the malignancy of the new growth can be predetermined. It would seem from clinical experience that the classification of Broders of malignant tumors has been of great value in this predetermination. Briefly, this classification is as follows, quoting from A. C. Broders (6) "It is the aim of the microscopist, in the grading of carcinoma and of other malignant neoplasms, to estimate the proportion of cells that are partially or completely differentiated on the one hand, and those that are more or less undifferentiated on the other. The results are expressed in numerals from 1 to 4, as follows. A carcinoma graded 1 is one in which the proportion of differentiated cells ranges from almost 100 down to 75 per cent, that of the undifferentiated cells from practically 0 up to 25 per cent, in a carcinoma graded 2, the proportion of differentiated cells ranges from 75 down to 50 per cent, that of undifferentiated cells from 25 up to 50 per cent, in a carcinoma graded 3, the proportion of differentiated cells ranges from 50 down to 25 per cent, that of the undifferentiated cells from 50 up to 75 per cent, and in a carcinoma graded 4, the proportion of differentiated cells is from 25 per cent to practically 0, that of the undifferentiated cells from 75 up to 100 per cent.

"At this point I should like to state that, as a rule, there is practically the same grade of malignancy throughout a carcinoma."

The function of the larynx is two-fold. Primarily, its function is as a valve placed at the upper part of the respiratory apparatus to prevent foreign substances from entering the airways. Secondly, in the process of evolution, the larynx has become the most important factor in the production of the voice.

Our method of attempted cure of a patient with carcinoma of the larynx must be so adjusted that consideration is given primarily to a permanent cure and secondarily to the conservation of function—that is the voice. Also, the results obtained by certain methods

must guide us in whether or not our procedure shall be conservative or radical.

Fielding Lewis (7) considers lesions located on the anterior part of the cord, as 80% curable when operated upon by laryngofissure.

St. Clair Thompson (8) considers that 76% of cures can be obtained by this method.

Tucker (9) has reported 92% of cures by laryngofissure, but in this report several of the patients had been operated upon within one year. However, most of them had been operated upon three years and many over four and five years previously.

Clerf and Crawford (10) are of the opinion that the cell type of a tumor should be considered in conjunction with the age of the patient, the location and extent of the lesion and the duration of the disease in determining the form of treatment to be carried out.

New and Fletcher (11) conclude that the selection of patients with carcinoma of the larynx for a conservative or radical operation should be based on the special type of lesion, in addition to the usual consideration.

Diagnosis

Hoarseness and the observation of a new growth on the vocal cord, should lead to the establishment of a diagnosis that will either prove or disprove of a cancerous lesion. The age of the patient, sex, habits as to tobacco and alcohol are to be considered. To quote from Butlin, "There are three classes of cases: first, in which anyone and everyone can make a diagnosis; second, in which the better instructed or more experienced can make, and the other do not; and the third class in which the conditions are so obscure that no one can make a diagnosis unless the larynx is open and in some of which it is even then difficult to be sure of the nature of the disease."

Sir Felix Semon (12) says: "Out of thirty-three patients on whom thyrotomy was performed for presumably intrinsic malignant growths, in eight, the diagnosis was either found to have been at fault or remained doubtful."

The patient must be properly x-rayed to exclude tuberculous infection, "his temperature, weight, physical signs, fatigue, blood and sputum, should be investigated." "Tubercu-

losis may develop in the larynx, and particularly in elderly and vigorous men, without any tubercle bacilli in the sputum and with quiescent or negative chest symptoms."

Establishment of the diagnosis must be done by biopsy and if possible the growth typed according to the Broders classification. Indirect examination should always be repeated so that proper observation and study may be given the growth. Direct examination and biopsy should be done, if possible, by the surgeon who will do the major laryngeal surgery—for by the use of the direct laryngeal speculum, he may observe the larynx that by the indirect method he may not have seen so well, either because of sensitiveness on the part of the patient or noncooperation. The ventricles and subglottic space may be inspected and the extent of the growth determined. When the biopsy is done, it is done with the precision of the operator who will later observe the larynx through an anterior opening, and especially if he is doing a thyrotomy.

Classification of growths in the larynx are intrinsic and extrinsic. Thyrotomy and laryngectomy are definitely indicated in intrinsic growths.

Intrinsic growths may be divided in anterior and midcordal growths with comparatively no infiltration of the surrounding tissues. In this type of growth, thyrotomy is indicated and provided the classification of the growth is not a number 3 or 4 of the Broders classification. If it is, it is very likely that a recurrence will take place. In all other growths that are intrinsic, that is, within the larynx, laryngectomy is indicated.

Laryngectomy is indicated and should be performed following a recurrence in one on whom a thyrotomy has been done.

The operation should be confined to growths within the larynx, that are of such a nature because of size, location, degree of malignancy and infiltration of the adjacent tissues, the conservative procedure of laryngofissure would not suffice. The end results will depend mainly on the adherence to these facts. In general it may be accepted that 5% to 8% of these patients operated upon by this method will have a recurrence.

Growths that have extruded themselves outside of the larynx or are postcricoid, occasionally may be helped by a laryngectomy plus type of operation, with a bloc dissection of the tissues of the neck.

Irradiation, following this extensive operation, has given some encouraging results.

Summary

Establishment of diagnosis must be done by biopsy and, if possible, the growth typed according to Broders' classification.

If the growth is localized to the middle or anterior portion of the cord, and is of type 1

or 2, laryngofissure or thyrotomy should be considered.

A growth of such size that it extends posteriorly or on to the adjacent cord anteriorly, even though it be of the 1 or 2 grading of Broders, indicates the necessity for laryngectomy. Growths in the posterior commissure also demand laryngectomy.

Growths that have extruded themselves outside of the larynx, occasionally can be helped by extensive operating. The lymph nodes are always involved. In these types of cases, laryngectomy accompanied by bloc dissection of the neck and later intensive doses of high voltage x-ray, have given fair results.

The laryngofissure operation performed is after the technique of Chevalier Jackson. The

technique in the laryngectomy operation is that essentially of MacKenty.

Conclusion

The names of Solis Cohen, Bruns, Chiari, von Bergmann, Kocher, Mikulicz, Schmieglow, Moure, Chevalier Jackson, Madyt, Scheier, Wassermann, Sendziak, Hoshine, Crile, Delavan, MacKenty and those others mentioned previously, are in that galaxy of medical stars that have shone so brilliantly in the fight against cancer of the throat. By their labor in these laryngeal problems, they have advanced our knowledge in diagnosis and improved our operative technique to its present status. We, of this present decade, salute them.

The Non-surgical Treatment of Aphonía (Hoarseness)

by

IRVING WILSON VOORHEES, M.D.

New York City

HOARSENESS is a symptom and not a disease. Therefore, we do not *treat* it at all, strictly speaking, but we do aim to treat the disability which expresses itself in loss of voice, partial or total as the case may be.

When I began to set down on paper some of the thoughts which came to me in preparing this little contribution to the discussion of hoarseness, I found that it is utterly impossible to consider it apart from diagnosis. Nowhere in medicine is it more important to determine the exact cause of a malady which is not immediately dangerous to life. And yet, hoarseness seems to signify to most physicians, merely laryngitis, nothing more. Moreover, there is too often not even an attempt to examine the larynx, and a wooden spatula held against an obstreperous tongue, under an insufficient light, makes the diagnosis. That is, to be sure, reprehensible, but we must remember that even in expert hands, the laryngeal mirror *sometimes* fails because of gagging or vomiting, or lack of cooperation of the patient. Personally, I have been at a disadvantage in some cases where a physician has sent a patient for an "expert opinion," and I have been unable to study the larynx with any degree of satisfaction, even after moderate cocaineization. It may be necessary to try at several different sittings before we can determine, with reasonable satisfaction, the various points upon which diagnosis rests.

Very frequently, the patient has had a respiratory infection of a generalized type, a real top-to-bottom affair, in which the larynx has borne much of the brunt of the attack because of violent coughing and the consequent insult to the laryngeal tissues. The sovereign remedy is compound tincture of benzoin, in-

haled from a steamer, and this certainly helps in the simple infections, nonvirulent types; but there are many other types in which it does little or no good, and may do harm by prolonging the period in which exact diagnosis is not made—even to a fatal outcome.

Here is an actual problem case. . . . A young business woman came down with a general respiratory infection which was diagnosed as "the flu." She lost her voice completely for two weeks, during which time she inhaled steam from benzoin three times a day, and visited her general physician every other day. The condition did not improve, however, and since she was unable to earn the usual honorarium as a church singer on Sundays, she became alarmed lest the voice never return and asked that she be sent to a specialist.

Examination disclosed a general respiratory infection with masses of yellow pus flowing down the postpharyngeal wall. The cords were covered with secretion and were reddened and swollen. There was also a tracheitis, as evidenced by engorged tracheal mucous membrane and secretion which was being constantly coughed up. Immediate attention was paid to the nasal condition. Metaphedrin, aqueous solution, one-half of one per cent ($\frac{1}{2}\%$), was prescribed to be instilled into the nose, five drops every three hours. Irrigations of normal saline three times a day to remove the excessive secretion were ordered, with special instruction as to the danger to the ears and how to avoid it. A cough sedative was given at night in order to insure much needed rest, and the inhalations were continued in order to help rid the lower airways of the profuse discharge. Daily treatments were given in the office which were cleansing and antiseptic

in nature. For the larynx and lower airways, I instilled, with a glass syringe, one c.c. of hexylresorcinol in distilled water (half and half). Strict silence was enjoined, and absolute rest in bed between visits. A specimen of sputum was obtained and sent to a laboratory which reported *Streptococcus hæmolyticus* and *Staphylococcus aureus* from which a culture was prepared for the making of a vaccine. It was my intention to give the vaccine if any complication such as joint or muscular infection supervened. This proved to be unnecessary, however, but in several previous experiences it has been of value in providing us with an additional weapon against this vicious unseen enemy—the *S. hæmolyticus*. On the fourth day, the lady came in with a cheery “good morning.” The voice was not normal to be sure, but it was present, to her great delight. It was two weeks from the beginning of my treatment before she was allowed to sing. During this time, a ferric tonic was given; for it is very important to restore the general physical condition in all of these cases. The best tonic would be a change of air, food, and sun baths out of doors, but this is denied to most patients in these troublous times.

When considering such an infection, one should keep in mind several possibilities. First, we may be dealing with an early pulmonary tuberculosis—one in which other vicious organisms prepare the soil for Koch's bacillus, and lower the vital resistance so that the implant gets in its deadly work at once. Moreover, there may be a lighting up of an old healed focus in the lung, the presence of which was unknown. Secondly, it has seemed to me that, in certain cases, the cropping out of such illnesses as “rheumatic fever,” gastro-enteritis, or even appendicitis may possibly hark back to the respiratory infection of some weeks or months before. In one instance, a persistent and continuing crop of boils on the legs and back, which were cured only after the use of a stock vaccine, made me think of the previous infection, but it was then too late to try to prove any connection. This may be entirely fanciful, but it does no harm to keep such an eventuality in mind.

In the case cited, hoarseness was a very minor consideration. It merely pointed the way to a careful consideration of its cause.

Hysterical aphonia, while fairly rare, has been seen by every laryngologist of experience. There is no history other than sudden severe loss of voice of undetermined origin. Examination reveals a bowing of the cords at the middle. Both ends may approximate quite well. I do not know that anyone has ever explained this medical curiosity satisfactorily. The neurotic factor, whatever it is, seems dominant, but the sudden recovery is little short of miraculous, and most of them do recover in a few days or weeks. It requires a sudden shock to bring about restoration of voice. Years ago, at the old Vanderbilt Clinic, I re-

member seeing the “hot spark” applied to the patient's larynx in two or three cases. The current used was strong enough to give a sudden contraction of the laryngeal muscles, and the patient uttered a sudden cry of fright, whereupon the voice became immediately normal. I have reported one curious case.* A man was referred to me by an insurance company with the history that while at work in a cellar, a step-ladder toppled over and knocked him down. When he came to, he was much surprised to find that he could not speak. The insurance company which carried the liability for his employer, referred him to me, and remembering the use of the hot spark, I sent him to an electrotherapist with the diagnosis and the recommendation for a “surprise attack.” This gentleman, through inadvertence, used the sinusoidal current instead, with no immediate result. But the patient, who lives on the east side of the city, made his daily visit on foot through Central Park. He was on his way to receive a fourth treatment when he was set upon by thugs who stole his wallet, his watch and his staff, and with the storied horse laugh, left him lying quite helpless. Thereupon, he set up anxious cries of Police! Murder! Thief!, and was quite amazed to find that his voice had returned. Examination the next day showed a normal larynx.

Hoarseness in singers is not infrequently caused by so-called Vocal Nodules. These are usually the result of bad singing, that is, faulty voice placement long continued. Or they may come on after singing “over” a laryngitis. The swollen cords no longer have a sharp vibrating edge and hence they must be squeezed together in order to function at all. This forcing seems to produce a condition similar to the rubbing which brings about a corn on a toe. At first, a tiny mucous gland, on the margin of the cord, becomes closed and we have what amounts to a retention cyst. At this stage, the condition is easily cured. Later on, however, the area becomes “organized” and a fibrous nodule results. In the early stage, daily applications of silver nitrate, beginning with one per cent and increasing in strength, can effect a cure. Vocal exercises also help to get rid of nodes, and there are teachers who claim that they can “sing off” these excrescences—any and all of them. I have yet to be convinced of this in those fibrous conditions where a structural change persists until removed surgically. Theoretically, at least, you cannot walk a corn off your toe, but by too much walking you can make it impossible to walk at all. Is not the analogy applicable to the vocal cords as well?

Instead of ascribing all aphonia to “just a cold,” we must bear in mind that the great diagnostic triad, malignancy, tuberculosis and syphilis stand ever ready to make fools of us. Worse than that is ultimate loss of a pa-

* Curious Cases in Ear, Nose and Throat Practice. The Medical Times and Long Island Medical Journal, November 1932.

uent's life through our lack of diagnostic acumen. Nonoperative treatment of this kind of hoarseness need scarcely be mentioned here, although physical therapy, radium, radiant light and heat and convective heat as well as roentgen ray may have a place at times. But radium, in laryngeal malignancy has been repudiated by many, if not most laryngologists—pre-eminently by the late Dr. John E. MacKenty, whose experience was wide and well-considered. To say that he hated radium in these cases is to understate the truth; for he despised it.

In the hoarseness of chronic laryngitis of infectious origin, where structural changes are not too pronounced, physical agents are of value. Electricity in its various phases has the support of many men of eminence. Both the Faradic and Galvanic currents have their supporters, and the infra-red lamp is much used, as is the vacuum electrode of the high-frequency current. The laryngologist, however, should have special training in these modalities before venturing too far, as troublesome burns and grievous accidents may arise from the unskilled use of such powerful agents.

Sudden severe hoarseness in singers is often due to a ruptured blood vessel within the cordal structure. Recently, a well-known opera singer became suddenly hoarse while "warming up" in his dressing room preparatory to going on. The stage was set and it was impossible to "change the bill" after the time-honored method of disappointing thousands of auditors who have bought tickets for a certain opera, only to be faced at the last moment by an announcement of a change. In this instance, another tenor who knew the role was promptly found and gave an extraordinary performance without rehearsal. He should have had a medal for his heroism in stepping into the breach and subjecting himself to possible unjust criticism. The newspapers reported that a sudden attack of "clergyman's sore throat" had brought about the singer's disability. This phrase has no place in medical parlance, although it is mentioned in most of the books. Insofar as I can find out, it means a pharyngitis with extension to the glottis, or in other words, infection with swelling of the cords due to excessive use of the voice. Although I have had no conference with the laryngologist who gave out this information to the press, I am sure that he merely used this phrase as a public pacifier, not wishing to commit himself to the actual diagnosis for obvious reasons. Beyond a doubt this was a case of hemorrhage into a cord, due to forcing the voice under adverse conditions—a beginning laryngitis, perhaps.

My reason for thinking so is based on an experience of some years ago. A vaudeville singer of repute became suddenly voiceless during an act where he was supposed to imitate a great tenor. He promptly left the stage and routed me from bed in order that I might

"tell his manager" when he could go to work again. Laryngeal examination showed the left cord suffused with blood. No sound came from the larynx upon effort to phonate while the mirror was in place. His manager was told that this condition would require two or three weeks for absorption, no matter what the treatment; but there was a blocked nose due to deviated septum, accompanied by a discharge of muco-pus into the nasopharynx (probably a low-grade sinusitis); and that the tonsils were also infected. It was proposed to treat the larynx and at the same time to do the necessary operating. In this way, no extra time would be lost and, when the larynx was again normal, the conditions which contributed to the strain would be absent. The singer did not take my advice, but went to a neighboring city where he was told that "the New York doctor was all wet." What was really required was an immediate tonsillectomy, as the hoarseness was entirely due to infected tonsils. Accordingly, this operation was performed, severe hemorrhage ensued, requiring a blood transfusion, and the singer was "off stage" for more than a year. I suppose I ought to give thanks for missing that one!

There are so many ways of treating acute laryngitis that it is useless to offer anything in the way of standardization. *Chacun a son goût*—each according to his taste, as the French have it. In Chiari's and in Menzel's clinic in Vienna, many years ago, I saw much use of cocaine in these cases. They used to drop ten to twenty per cent into the larynx every day. This, of course, relieved the cough, temporarily, but I have often wondered how many of these poor people became addicts as a result.

At one time I used menthol in albolene, a 5% suspension dropped into the larynx. It was efficient but caused such a burning sensation that it was discontinued.

Lozenges, troches and all the great company of such medicaments ought to be taboo among physicians, even if they do appeal to the laity because of their convenience, etc. They upset the stomach and do little to effect relief. Rather, recommend the old-fashioned honey, molasses, candy or pineapple juice of our grandfather's day. As an instillation, guaiacol in albolene, from 2 to 5%, helps both the larynx and trachea. One-half c.c. dropped in daily, is enough as a rule. If a gargle seems desirable, I recommend Hexylresorcinol, from 50% aqueous solution to full strength.

I am convinced that the course of these acute conditions is measurably shortened by rest in bed, or at least on a couch most of the time; from eight to ten hours sleep; and plenty of good, wholesome food as afforded by a mixed diet. Common sense demands elimination via the emunctories. We all have our favorite ways of bringing this about.

Benign Neoplasms of the Larynx

by

DANIEL S. CUNNING, M.D.

New York City

STRICTLY speaking, the above title might be considered to include all benign tumors of the Larynx, regardless of their etiology, in which case it would be necessary to discuss such general conditions as Tubercle formations; Gumma, etc. However, since these conditions have been so thoroughly taken up in a previous paper, it is the intention of the writer to limit his talk to Benign Tumors of the Larynx as considered in the narrower sense. Among such Benign Tumors may be mentioned the following:

Papilloma, Polyp, Vocal Nodules, Contact Ulcers, Fibroma, Cystoma, Lipoma, Adenoma, Myoma, Lymphoma, Chondroma, Osteoma, Varices, Mycosis Fungoides and Thyroid Tumors.

A large percentage of these are so rare as to be unworthy of serious discussion. As, for example, the Thyroid Tumors of the Larynx mentioned by Jackson, who, in his large experience, has seen only eleven cases. With your permission, therefore, I will limit myself to the following, frequently seen, Benign Tumors, viz: Papilloma, Polyp, Varices, Hematoma, Fibroma, Lymphoma, and one of the most important, the ordinary nodules so frequently referred to as Singer's node.

Symptoms of Benign Tumors in the Larynx vary markedly, depending on the size and location of the tumor. When on one of the true or false cords, hoarseness occurs very early, and is usually the most common complaint, and frequently will be the only symptom present. However, even hoarseness may be absent in some tumors, as in growths on the epiglottis arytenoid, or any of the more roomy portions of the Larynx. Among the other symptoms frequently seen are dyspnea, cough, croup tendencies and occasionally pain.

Papilloma

Of all the Benign Tumors of the Larynx, Papilloma appears to be by far the most important. It must be borne in mind that there is a distinct difference, histologically and clinically, between Papilloma and Polyp, and yet, frequently enough, care is not taken to differentiate between these two terms in our ordinary diagnostic nomenclature. Histologically, a Polyp is an edema of the connective tissue beneath the epithelium, bulging it out, and, as a result of pressure, the epithelium becomes thin and nonpapillated. It is usually associated with thrombosis and varicosities of the veins, quite analagous to Hemorrhoids. In marked contrast to this picture is the histological appearance of a Papilloma which shows

a papillary hyperplasia of the surface epithelium, but the basement membrane remaining intact. It is quite analagous to a cauliflower growth.

In childhood, this condition is most frequently seen as a multiple papilloma, while in adult life the single papilloma is more common. The usual history of papillomata in childhood is as follows: the mother states that the child, for some months past, has been having increased hoarseness, after which a gradually increasing difficulty in breathing has been noticed. Many things, such as enlarged Tonsils, Thymus, etc., must naturally be considered. On a cursory examination, no explanation will account for the condition. A mirror examination is impossible on account of the age of the child, but direct Laryngoscopy immediately reveals that there is a multiplicity of Papillomata springing from the true and false cords. It is too frequently forgotten that Papilloma of the Larynx in childhood is usually self limited, and will ultimately cure itself. In olden days, the treatment consisted of a semi-permanent Tracheotomy, the tube being removed when the laryngeal breathing was reestablished, the time usually amounting to upwards of five years. With our modern technic with the use of the Laryngoscope, the logical treatment is repeated removal of the Papillomata as they recur, being particularly careful not to damage in any way the important and permanent structures of the Larynx. It cannot be too strongly emphasized that the true and false cords or the Arytenoids, must not be sacrificed in this removal, and if any error must be made, it must be done on the side of the Papilloma. Occasionally, even in childhood, a single removal of Papillomata will effect a permanent cure. Resorting to Tracheotomy for this condition, must, if possible, be avoided.

It is apparent to clinicians that the occurrence of multiple Papillomata in children has been on the decrease for the past ten or fifteen years. This may possibly be accounted for by the more modern understanding of diet during infancy and early childhood, combined with a more careful study and treatment of the sinuses, tonsils and adenoids.

In the adult stage this condition is more frequently seen as a single, isolated Papilloma, and with a single removal, preferably by direct Laryngoscopy, a permanent cure is usually effected. However, at times, a multiplicity may occur even in the adult stage. Should this condition be recognized, the treatment is exactly the same as in childhood, but it must always be borne in mind that, occa-

sionally the papillomatous growth will invade the underlying structure (submucosa), and change characteristics, even to such a degree as to eventually take on a true malignant form. To express this in simple words, chronic, multiple Papillomata may at times be the forerunner of a true malignancy of the Larynx, and must be considered with a certain degree of apprehension. In the opinion of the writer, and regardless of modern theories, the clean-cut surgical removal of these Papillomata is far superior to the questionable treatment with electro-coagulation, radium, x-ray or similar applications, as these latter cannot be measured to so definite a degree, and offer no more, in so far as recurrence is concerned.

Polyp

Clinically, in contradistinction to Papilloma, it most often occurs as a single, elongated, glistening mass, usually hanging by a definite and thin pedicle. It has a marked tendency to alter its position during forced breathing, and may at times almost entirely disappear from view by assuming a subglottic position. Tendency to recur is rare, and simple removal usually effects a permanent cure.

Hematoma

Only a brief mention of Hematoma must be made. This condition is a simple extravasation of blood with ultimate formation of blood clots beneath the mucous membrane of any portion of the Larynx. It is commonly seen as the result of Trauma to the Larynx, as in choking, violent coughing, or any similar type of injury sufficient to produce bleeding, but in which the blood has not actually penetrated the surface mucous membrane. Unless the actual tumor formation is large enough to produce a mechanical breathing obstruction, the Hematoma should not be surgically interfered with, as the blood clot will ultimately be absorbed. Complete rest of voice, ice packs to neck, and the possible use of potassium iodide to encourage absorption, should limit the attempt at treatment.

Varices

Varices are enlarged tortuous veins, arteries or lymphatic vessels, with the Venous type predominating. This latter type of Varix, according to an extensive study by Imperatori, is pathologically identical with an ordinary hemorrhoid.

This condition usually appears as a small, bright red, bead-like tumor along the surface of one of the true cords. Occasionally it is

pedunculated. As the name implies, it is the result of a collection of small blood vessels, which have assumed such a definite outline as to demand consideration as a true neoplasm. The growth may advance to much larger proportions, so that a fair section of the Larynx may be involved. As in the case of Hematoma, this tumor is usually the result of the acute faulty use of the voice, as in shouting. The term acute is mentioned as causative factor in contradistinction to the chronic faulty use of the voice which is much more prone to produce a Singer's node. Varices are essentially benign, and when treated by simple surgical removal under Direct Laryngoscopy, leaves the cord in normal condition as far as function and appearance are concerned, with little tendency to recur. The more modern theories advance the possibilities of Radium, or the removal with Diathermy. Applications of Radium are rather difficult in any Laryngeal lesion. The treatment by Diathermy must be considered. It would seem that, except under unusual circumstances, a direct removal is more simple and accomplishes the same result.

Fibroma

This condition may be dispensed with in a few words. It usually occurs on one of the cords, but may appear in any portion of the Larynx and, from an etiologic standpoint, in the majority of cases, no cause can be discovered. Only two symptoms are present. In the smaller type, and those located on the cords, hoarseness is always present. But if the tumor assumes larger proportions, interference with respiration will ultimately develop. Surgical removal by Direct Laryngoscopy is the safest, and logical method of treatment. Recurrences are extremely rare.

Lymphoma

This type of tumor, when not associated with a general Lymphomatosis, is practically always benign. This condition is uncommon; it usually occurs as a single tumor, and it may be considered as the only benign tumor in which surgery is contra-indicated. The external application of Radium brings about a total disappearance of the tumor, and when properly applied, the normal structures of the Larynx are unharmed. The tumor, as a rule, does not recur after removal.

Singers Nodes

This condition, which has been so frequently discussed, still remains in the category of the more or less unsolved problems, so far as the

outcome is concerned. It has been recognized for many years that individuals who constantly use their voices, such as singers and orators, are frequently the unfortunate victims of a gradually increasing hoarseness, which in some instances becomes so marked as to definitely interfere with their careers.

As a result of this observation, it gradually became apparent to clinicians that the actual production of voice must be the underlying cause, and further study definitely indicated that when the voice is in more or less constant use under unusual circumstances, a proper method of delivery is essential, or hoarseness will result. With the coming of the Laryngeal mirror, it soon became apparent that, in these individuals, a pathologic change had taken place in the true vocal cords, namely the formation of a small but definite nodule appearing on the contact surface of one or both cords. About this time, consultations between vocal instructors and Laryngologists offered several interesting observations. First and most important it was noted that these nodules appeared in singers who were attempting to perform in the wrong register. As for example, the low soprano endeavoring to take the notes only natural to an extremely high soprano, and *vice versa* on the other end of the scale. It cannot be too strongly emphasized that the range of every human voice is limited. A tenor cannot attempt to go into a range too low for his natural anatomical abilities. On the same basis, a voice which is small in volume, must not be forced to assume the large, vibrating, and forceful type. Any attempt to disobey the above mentioned facts over a prolonged length of time will often result in a gradually increasing hoarseness, until eventually the entire quality and characteristics of the original tones are lost, and replaced by a rasping, harsh and extremely unpleasant sound. A further study in conjunction with the vocal instructors, made it apparent that these nodes most frequently appear when there is an attempt on the part of the singer to adopt a register lower than his natural tone. This observation applies not only to the singer but to the orator as well.

Pathologically, a singers node consists of the piling up of the surface or epithelial cells of the true cord on its contact side. It may occur on any part of the cord, but it is most prone to occur on the anterior third when the register is abnormally high, and on the posterior third, when dealing with the lower type of voice. These nodules must not be regarded as true Papillomata and consequently a single removal does not necessarily effect a cure. They must be regarded rather as a definite entity and from the singer's standpoint, their seriousness lies in the fact that they are almost always associated with a lack

of true coordination of the delicate muscles used in the normal production of voice.

Treatment

Reviewing the history of any definitely established singers node, it becomes apparent that the degree of treatment will entirely depend on what stage the condition is seen in. If the case is seen in the early stages, no nodule will be visible on either cord, but nevertheless, the patient will show vague, indefinite throat symptoms and minor changes in tone when compared to what was his normal voice. These warnings, such as too frequent efforts to clear the throat during unusual voice activity, etc., will gradually increase until a temporary, and finally a permanent, hoarseness will appear. It is obvious that the treatment must depend upon the stage in which the condition is first observed. In general, it can be said that the first and most important fact to be borne in mind, is that the underlying cause must be eliminated. This fact cannot be too strongly emphasized, and a thorough mutual study, between the Laryngologist, patient and vocal instructor, should determine what abnormal vocal effort is being made on the part of the patient. Frequently it will be found that too large a range is being attempted, or as mentioned above, the register is unsuited for the particular Larynx. Having determined and corrected this abnormality, the second essential is complete rest of voice, often times for a period of years. This procedure alone, in the reasonably early cases, may bring about a cure unless the individual again proceeds to abuse his voice. In the more advanced type of case, and in one in which a nodule is actually visible, a difference of opinion exists as to the proper procedure.

Many excellent Laryngologists insist that no surgery is indicated, and that the only treatment still consists in correcting the cause, and placing the Larynx at rest. However, in the opinion of the writer, when a fair sized nodule is actually present, coaptation of the cords is impossible, and even with prolonged vocal rest mechanical irritation still exists, so that the condition will rarely cure itself. This is particularly true, if one remembers that even during the normal process of breathing, the vocal cords do not remain stationary, but rather are in more or less active motion, even though the patient completely abstains from talking.

It would seem, therefore, that in this latter type of case, the actual shaving off of the nodule or nodules cannot be considered too radical, naturally assuming that great care is taken not to injure the true cords. Following this procedure, rest and the ultimate proper replacement of the voice is essential.

Tuberculous, Malignant, and Syphilitic Types of Hoarseness

by
DAVID H. JONES, M.D.
New York City

HOARSENESS is the common symptom of tuberculosis, carcinoma, and syphilis. During the past five years, with better methods of examination and constant education of the laity, earlier diagnoses are being made in laryngeal cancer, and as a result of this the present percentage of cures, which is now seventy to eighty per cent, undoubtedly will be higher.

Six per cent of all malignant tumors occur in the larynx. These are classified as ninety-eight per cent carcinoma, and two per cent sarcoma. A further grouping shows that ninety six per cent are squamous cell varying in malignancy, two per cent basal cell, one per cent papillary carcinoma, and one per cent adeno-carcinoma.

Depending on location and extent of disease, which is of extreme importance surgically and prognostically, we recognize clinically, extrinsic, borderline intrinsic, and intrinsic.

The extrinsic group includes cancer whose origin is from the epiglottis, arytenoid, ary-epiglottic fold, the laryngeal surface of the pyroform fossa, and the pharyngeal surface of the cricoid cartilage. This group rarely gives

any warning, and our earliest symptoms are local discomfort and dysphagia, no change in voice, and metastases occur early.

Borderline intrinsic is advanced intrinsic cancer, slow and superficial growth, extension downward and forward, not upward and backward, low degree of malignancy, and in this group, with our improved operating technique, more patients are being operated upon with very good results.

The intrinsic group includes all cancers arising from the cord, ventricular band, interarytenoid region, and the subglottic area. And we subdivide these further into anterior intrinsic involving anterior two thirds of larynx, and a posterior group including the posterior third of larynx. The earliest symptom in the anterior group is hoarseness, and in the posterior group we find hoarseness and local discomfort.

In order to give one a clearer idea of the differential diagnosis in these diseases the writer has placed the corresponding conditions and appearances, as far as possible, in parallel columns, remembering that one may encounter two or even three diseases in the same patient.

SUBJECTIVE SYMPTOMS

TUBERCULOSIS	CARCINOMA	SYPHILIS
Hoarseness (mild to complete aphonia)	Hoarseness Progressive (90%)	Hoarseness (secondary stage)
Recurrent aphonia, also dysphonia	Recurrent aphonia, also dysphonia	Recurrent aphonia, also dysphonia
Both sexes	Males, females postcricoid	Males
Age under 40	Age 20 to 80 years	Age not constant
Always secondary to lung involvement	_____	_____
Voice weak, hollow, painful	Voice easily fatigued painful	Voice rough, raucous, pain less, tertiary stage
Odynophagia for solids in ulceration of epiglottis and ary-epiglottic folds, for liquids in muscle involvement	Odynophagia, extrinsic	Odynophagia late, ulceration of gumma
Hyperaesthetic	Ulceration painful	Anaesthetic
Cough	None	None
Expectoration	None	None
Emaciation early	Emaciation late	Emaciation late
Enlarged glands, occasionally tender	Enlarged glands, hard, fixed in extrinsic	Glands rarely enlarged

Before mirror examination, throat and larynx should be anesthetized with either 4 or 10% cocaine to abolish reflex. Ample time should be given for anesthesia to become

effective. One cannot stress too strongly the need of very careful examination, as many physicians and otolaryngologists do not take the time to make a proper diagnosis.

OBJECTIVE SYMPTOMS—MIRROR EXAMINATION

TUBERCULOSIS	CARCINOMA	SYPHILIS
Pretubercular stage difficult to recognize.	Precancerous stage	Acquired form, primary sore rare.
<i>Pharynx</i> : pallor and anaemia.	No change	Mucous plaques, gumma scar formation.
<i>Larynx</i> : mucous membrane often pale red.	Mucous membrane (non-inflammatory)	Mucous membrane vermillion.
<i>Epiglottis</i> : Laryngeal surface infiltration, oedema, ulceration (turban shape).	—————	<i>Epiglottis</i> : lingual surface.
<i>Post-commissure</i> : thickening, irregular, seen on phonation.	1. Persistent congestion and thickening of cord. 2. Definite tumor.	Hyperaemia, congested, generalized inflammation, mucous patches, gumma may form and break down forming ulcers.
<i>Arytenoids</i> : smooth, oedema, usually bilateral.	3. Limited infiltration, cupped or retracted. 4. Sessile, white or reddish gray tumor. 5. White fringe like border on cord.	
<i>Location</i> : posterior third, slow growth.	<i>Location</i> : anterior two-thirds.	<i>Location</i> : anterior third.
<i>Bilateral</i> : general rule.	<i>Unilateral</i> : slow growth and metastases. No distinct line of demarcation.	<i>Bilateral</i> : rapid growth.
Ulceration early.		
Ulcer on cord and elsewhere, pale, superficial, moth eaten, edges inactive, (<i>nibbles</i> .)	Ulcer, raw, red, overgrown edges, dirty white on cords.	Ulcer, dirty drab, punched out, undermined, (<i>bites</i> .) little tendency to heal.
Not much deformity.	Unilateral fixation of cord.	Acute oedema and cicatrization may cause stenosis and dyspnoea.
Immobility of cords late.	Loss of mobility, second symptom.	Fixation left cord. Aneurism is most frequent cause.

The night before direct laryngoscopy the patient should be given a sedative (allonal, luminal or amytal) and repeat the morning of operation. One hour before operation a hypodermic of morphine sulphate grs. $\frac{1}{4}$ and hyoscine hydrobromide grs. $\frac{1}{300}$ should be

given, and cocaine anesthesia as outlined in a preceding paragraph. Some patients will require general anesthesia.

All laryngeal growths are found to be much more extensive when seen by direct than by indirect laryngoscopy.

ABSOLUTE SILENCE AND ABSTENTION FROM ALCOHOL AND TOBACCO FOR TWO WEEKS—REPEATED ROUTINE MIRROR EXAMINATION—DIRECT LARYNGOSCOPY

TUBERCULOSIS	CARCINOMA	SYPHILIS
Biopsy sometimes necessary. Remembering danger as punch forceps force bacilli into tissue, scar wound after removal of section.	Biopsy repeated if necessary. Report from two pathologists. Positive report must be backed by clinical evidence. $11\frac{1}{2}$ months.	Biopsy rarely necessary. Obtain history, primary sore, skin eruptions, Wassermann. Examine septum, soft palate for loss of tissue, scarring, quick response to treatment.
Complete physical and x-ray examination, temperature, repeated sputum examinations.	Careful x-ray study neck and chest.	—————

Lantern slides were used with this talk.

In conclusion I can only reiterate what Dr. Chevalier Jackson has stated, and that is, there will be fewer deaths from laryngeal cancer when every member of the medical pro-

fession realizes the frequent malignant nature of chronic hoarseness.

Etiological Factors of Mammary Cancer in 200 Women

Also a Control Study of 100 Normal American Women

by

FRANK E. ADAIR, M. D., F. A. C. S

Attending Surgeon, Memorial Hospital,
New York City

Read before the Section of Obstetrics and Gynecology
at the Annual Meeting of the Medical Society of the State
of New York, April 5, 1933

TO obstetricians and gynecologists, the subject of cancer of the breast is one of great importance, particularly the phase dealing with its etiology. The obstetrician is confronted with the varied practical problems of the care of the breast during the months before parturition; and again with the post-partum breast management.

In 200 consecutive cases of cancer of the breast, we have made a detailed study† relative to pregnancy, miscarriage, nursing history, abscesses of the breast, "caked-breast," nipple inversion, "sore nipple," etc. A study of these points has brought us to the conclusion that *breast drainage* and *stagnation* are factors of prime importance relative to the subsequent development of breast cancer. To test the validity of this conclusion, a control of 100 patients‡ whose complaints were other than mammary, were contrasted. This comparison emphasized stagnation as an important contributory agent to the development of mammary cancer. To test this stagnation theory, Halsey Bagg§ in our laboratory took laboratory animals and subjected them to artificial stagnation by ligation of the nipples and by breeding experiments. The striking results of these animal experiments, together with the detailed histories of the control cases and the cancer patients, seem to fully justify us in our final conclusion that an important relationship exists between stagnation and the development of mammary cancer.

To some, the facts as brought out, may be at variance with your clinical impressions. But, on the other hand, it must be pointed out that few of you have a large experience in the study of breast cancer because of the fact that the patient with breast cancer, more commonly consults the general surgeon or cancer specialist about twenty to thirty years following the time when the obstetrician

took care of the patient. The problems brought out in these studies are numerous, striking and suggest a wide field for investigation. They strongly emphasize the "stagnation theory" of mammary cancer.

STAGNATION THEORY

By stagnation of the mammary system we mean that certain definite mechanical factors produce partial or complete blockage of the duct at some place situated between the periphery (the acini) and the nipple terminus (the estuary of the duct). Such an obstruction may be due to one of many factors. Let us examine a few which may enter into the production of breast stagnation

1 A localized outgrowth of the lining epithelium at some position along the mammary system causes stagnation and obstruction behind this point

2 The condition of the nipple (a) Some nipples are inverted and are pulled backward as if the terminal ducts were not long enough to allow for the normal nipple protrusion, (b) Other nipples are bivalved, there being a transverse depression across the widest diameter producing an acute angulation of a number of terminal ducts within the nipple itself. Inverted nipples more commonly have excessive moisture, redness, and a low grade chronic infection, than those nipples which normally protrude. Such inflammation and edema produces a marked stenosis of the terminus. (c) Another type is the partially inverted or 'puckered' nipple, this is similar to a partially inverted finger of a glove. (d) The 'flat' nipple is flush with the surface of the areola. This type seems to be *adherent* as if held down by adhesions. The normal protruding nipple is not "stuck." It can easily be pulled out by the fingers for nearly a centimeter. (e) The dwarfed nipple is very hard, small white, the type typical of the "spinster's nipple." By pumping this nipple I have never been able to obtain any fluid in a single case. They usually have a narrow and inconspicuous areola. This fibrous nipple has its terminal ducts greatly stenosed. (f) The ulcerated nipple the mucoid material extruded from certain nipples, sticks tenaciously on the nipple surfaces, so that in removing it, a bleeding raw surface is uncovered. Inflammation and resultant fibrosis produce stenosis and partial obstruction. In the series of 200 cancer cases, the congenital inverted nipple was present in 10 cases (5 per cent)

3 A fibrous scar across the ducts, the result of an incision for abscess or a contractile scar secondary to a traumatic hematoma, causes obstruction

4 The formation of a cyst (miniature or

larger), a fibro-adenoma or a localized inflammatory nidus within or without the duct causes obstruction.

5 A localized obstruction such as a plug produced by a collection of desiccated, desquamated lining cells. (Fig. 1).

6 The epithelial debris plugging up the duct estuary (Fig. 2).

7 Other causes

By the retention of the desquamated lining cells, mucoid material, cell detritus, etc., we

assume that an inflammatory reaction is set up in and about the duct system. Infiltration by lymphocytes and polymorphonuclear leukocytes takes place. The nature of this irritation is thought by Geoffrey Keynes in his distinguished article on "Chronic Mastitis" to be chemical. The cellular detritus together with products of degenerated milk (as in a case of recent pregnancy or miscarriage) lie within

the ducts and acini. We believe the reaction on the part of the tissues is to stimulate the duct lining cells to hyperlastic changes; these lining cells multiply and heap up several rows high giving the appearance of precancerous tissue. Intraductal papillomas¹ are formed (Fig. 3). We believe that the precancerous areas continue their growth and terminate by invasion and infiltration—with the development of true cancer.

When one attempts to span the space between the precancerous lesion and true cancer, he is then on much disputed soil. Exact proof is difficult. However, every pathologist has seen many microscopic fields showing a minute point where the precancerous lesion is just beginning to invade surrounding tissue. It is exactly at this point of invasion where the lesion turns cancerous.

ANATOMY

The breast is an organ suspended from the chest, consisting of from 15 to 20 separate and distinct terminal ducts, each duct having its own ampulla, and its main duct, ductule, and acinar system. The different systems do not communicate with each other. The ampulla, an elliptical or oval expansion of the terminal duct, lies within or at the edge of the areola. Cheate states: "From the ampulla the duct continues its course for about a centimeter and divides into two main branches. One of these passes backwards towards the chest wall, and the other is distributed to the periphery and is parallel with the surface of the breast."

FUNCTION

In the active as well as the inactive breast,

the normal cell regeneration or replacement process continually takes place. The desquamated cells lie free within the lumen of the ducts and acini. In the case of the virginal breast, the lumen contains degenerated desquamated cells, cell detritus, mucoid material, and some crystals. This cellular detritus, mucoid material, etc., are gradually pushed along from the acini to the terminal duct, and ex-

⁴ Cheate and Cutler: Tumors of the Breast. J B Lippincott, Philadelphia, 1931.

truded at the nipple. There is probably a resorption of some liquified material. However, one can occasionally obtain a watery secretion by gently stroking the duct and by the use of the breast pump. This is true not only of the multipara but also of the nullipara. This is contrary to the view of many who hold that there is no secretion from a normal breast. Women are unconscious of any such secretion, possibly because it is slight in amount, and because it evaporates as does perspiration and any residue is rubbed off by the clothing. However, anyone who observes carefully and has an opportunity to examine a large number of breasts will not infrequently note this secretion from one or more ducts

every lobule increases to several times its virginal volume and this, together with possible formation of new lobules, causes the breast to become tense and increased in size "During a large part of the period of gestation, the glandular or parenchymatous tissue continues to develop, while the adipose tissue, pressed upon, slowly disappears by atrophy until the entire mamma is sometimes composed of the glandular tissue"

The breast is greatly increased in volume by the formation and extension of new ductules, and by the creation of millions of new cells lining the new acini and ductules. Each new cell created in excess of the original number present during the inactive period of the

FIG 3—SHOWING THE INTRADUCTAL PAPILLOMAS are the result of continued irritation

We believe these hyperplastic manifestations frequently (From Cheate and Cutler, Fig 47 p 103)

On the other hand in the physiological active breast, not only is the above process taking place, but the extrusion of desquamated cells into the lumen is occurring at a very rapid rate. Deaver and McFarland³ state that during pregnancy "it is certain that in each already existing lobule further growth takes place in the form of many small pocket-like extensions from the tips and side of the alveoli or ductules, thus originating the true glandular acini." They also state that thus

breast must eventually be extruded. These cells are suckled out by the infant and are present in the milk. The amount of milk secreted by the physiological processes of the lining epithelium varies enormously; in one extreme there may be but a very small amount of milk secreted—while, on the other hand, there may be a huge amount—a condition known as galactorrhoea. In a case of a young woman in Japan reported by Remy⁴ six and one quarter quarts of milk a day were taken

³ Deaver and McFarland: The Breasts. P. Blakiston's Son and Co. 1917 p 11

⁴ Remy: Med Times and Gazette 2 581, 1883

It is thought that both the amount of new glandular tissue produced during pregnancy, as well as the amount of milk secreted, depend upon the hormonal stimulation of the breast. A normal amount of milk per day (possibly a pint to each breast) if locked within the breast, would contain such an amount of fat crystals, proteids, fatty acids, milk sugar, etc., as to be of considerable volume of solids, even though the mammary system may have taken up the water from the milk by resorption. It is these solids, together with the volume of desquamated cells imprisoned within the breast, that are subsequently responsible for the low-grade chemical inflammatory reaction on the part of the breast.

All mammals have their normal period for suckling their young; and it seems more than likely that the human is not meant to be exempt from this function—nor do I believe it desirable either for the baby or the mother, that this physiological process be interfered with, unless there is some definite contraindication. My personal impression is that physicians too easily permit the mother to feed the baby on the bottle because of the inconvenience of nursing, and call in a pediatrician to supervise the feeding.

Many times the economic status of the mother makes it nearly impossible for her to nurse the child, as she must work away from home to earn a living. One can comprehend and sympathize with the causes and excuses given for not nursing.

Clinical experience adds to the weight of the stagnation theory. We know that it is frequently possible to release the obstruction which produces a localized area or segment of mastitis. The procedure must be delicately carried out. It consists in first gently kneading vaselin well into the nipple in order to soften the miniature plugs of epithelial debris (Fig. 2) situated in the terminal duct estuary. Following this, the nipple is carefully washed with soft cotton and soap. The nipple is then rolled between the forefinger and thumb, and washed again. The plugs are released and are large enough to be seen with the unaided eye. One then gives a gentle stroking motion from the periphery of the breast toward the nipple, over the localized area of mastitis. Following this one uses the bulb pump or electric breast pump¹. In many instances, cases of localized mastitis so treated have cleared up promptly. The two following cases illustrate the point:

The patient, E. T., aged 37, first came to us February 3, 1926, with a mass 6 by 3 by 2 cm. It was thought to be localized mastitis. Six months later she returned, when I pumped the

breast and obtained from each of the five ducts, a thick creamy material similar in consistence to "cold cream." Dr. Ewing's report on this material was "mucus, fat, desquamatic, hydropic epithelium." When next seen twenty-six days later, the tumor was entirely gone. It had been situated in the outer upper quadrant. We had succeeded in withdrawing the material, and following this, the inflammatory reaction subsided. This patient was the mother of three children. The first two she had nursed. The last one born thirteen years ago was not nursed. The milk products and cellular debris of the last pregnancy had been locked up within the mammary system.

Another patient, A. M., age 42, came to the Memorial Hospital presenting the evidence of bilateral chronic mastitis (not localized). She had had four children and one miscarriage. The patient had only nursed her first and second children, not the third and fourth. The last child was 4 years old. The terminal ducts were very large, in fact, one or two almost admitted the tip of a filiform bougie. The breasts were pumped. From the right breast one-third of a test tube of creamy material was withdrawn from about eight ducts. From the left breast a thick pasty material came from one duct (Fig. 4). While pumping these breasts for some weeks, much material was withdrawn. The heavy breasts became smaller, the symptoms of heaviness and discomfort disappeared.

We carry out this treatment on all such cases in the breast clinic. However, as a warning, one must be certain that he is not dealing with cancer. It must be stated that we succeed in clearing up mastitis by this method in only a proportion of our cases. The type most liable to meet with success is that of (a) the multipara; (b) the case where the mastitis is segmentally localized; (c) the case where the cellular detritus is soft creamy material,

FIG. 4.—SHOWING THICK CREAMY MATERIAL ON A MICROSCOPIC SLIDE.

The material had the appearance and consistence of "putty."

in consistence not unlike putty (Fig. 4). It usually takes about a month for the breast to return to normal after this treatment. The quadrant most frequently drained by this method is the upper outer quadrant where the "tail" of the breast lies. Here the distance from periphery to the nipple is much greater than in the other quadrants.

In a few cases where it has been even as long as ten years since the birth of the last child, we have been able to obtain as much as 10 to 15 c.c. of creamy material from one breast by pumping. Some of these cases have sensitive heavy breasts; and following the removal of

¹ Adair, Frank E., and Pack, George T.: The Use of the Breast Pump as a Prophylactic Measure Against Secretory Stagnation in the Breast; and Possibly Mammary Cancer. *Ann. Surg.*, July, 1931, p. 154.

cancer cases (see Table I) there were 74 (37 per cent) who were either not married, or if married had never borne children. We know from the reports of England, America, France and Germany that cancer of the breast occurs more frequently in those who have never had children, than in those who have borne children. It also occurs at an earlier age. The only explanation which I have to offer for this group, is that the breast of the typical spinster, has an underdeveloped, small white, hard, fibrosed nipple which is the probable site of the obstruction to the mammary system. Fibrous mastitis is also more common in the unmarried than in the married. If one in his practice sees many cases of breast pathology, he will become familiar with the typical appearance of the "spinsters' breasts." The areola is rather pale and narrow. This breast is frequently the site of fibrous mastitis which is usually bilateral. Such fibrosis of the breast and nipple produces stasis which in turn causes the tissue changes leading up to cancer.

In this group of 74 cases, 3 had inverted nipples; one patient had received a profound injury to the breast; and one remarkable case (Case 15) had had five operations on the affected breast. The first operation occurred at sixteen years of age when a fibrous tumor the size of a hen's egg was removed. She was later operated at the ages of 30, 33, 36 and 40 years, respectively, at which time she was found to have a carcinoma. It takes but little imagination to conceive that numerous surgical insults would produce marked duct damage, fibrosis and stagnation peripheral to the scars.

Women in Whom the Normal Breast Function Had Been Established:— 1. Of the 200 cases only 17 (8.5 per cent) gave an absolutely normal nursing history. We consider this low figure as very important evidence supporting the stagnation theory.

2. Twenty (16 per cent) of the 126 women who bore children, never nursed. One interesting patient (Case 4) bore 19 children including three pairs of twins. All were bottle babies. The mother states that she never nursed because her physician told her that her milk was "dirty." Her first child was born when the mother was but sixteen years of age. By the time she was forty-four years old her mammary cancer was well developed. After such a mammary history how striking must have been the various pictures of stagnation!

In this group of cases a large volume of milk was bound and locked within the mammary system to degenerate into its end products. This was also true of the millions of newly formed lining cells which eventually desquamated and lay free within the lumen, to undergo disintegration and become a source of chemical irritation.

3. Eleven patients (9 per cent) of the 126 women who bore children, nursed for less than three months. One must not criticize this group as much good was accomplished during those weeks of nursing, especially in the par-

tial clearing of the mammary system. The percentage (9) developing cancer seems to have been reduced by the fact that the breasts functioned normally for a period of several weeks.

4. Thirty-one (20 per cent) of the 126 women with children, nursed part but not all of their children. Various reasons were given for this. Typical histories of this group are such as that of Case 60 who stated that she nursed the first child but not the second. Case 93 stated she nursed three children from eight to twelve months each but not the next child. From this, it would appear that it is better to nurse for a time, even though a short time (9 per cent) than not to nurse at all (16 per cent) or only nurse part of the children (20 per cent).

5. Seven cases (6 per cent) of the 126 cases had what might be considered an excess number of children. I am not sure what comprises an excess number but the number of pregnancies was far above the average. The only way that one could attach the large number of pregnancies to dysfunction, would be in that the normal readjustment period for the breast is not reached. One pregnancy promptly follows another. The new pregnancy is established before the breast is thoroughly drained. In Case 20, the patient had eleven children and one miscarriage. Case 42 had fourteen children during twenty-five years.

6. Twenty-six cases (20 per cent) of the 126 cases bearing children had some unusual factor which seemed to have an important bearing on the nursing and drainage history. This is a miscellaneous group; and only a few factors will be mentioned. Case number 57 had a miscarriage followed later by the birth of five children, then later four miscarriages. A lump appeared during the first miscarriage which always caused difficulty in nursing. Case number 62 developed a caked breast on the same side where the carcinoma later developed. Four patients developed caked breasts. Three developed abscesses that had to be incised. Two always had sore, tender nipples.

7. Miscarriage.—The 126 mothers bore 386 children, and had 172 miscarriages. This gives the high proportion of 31 per cent or one-third of the pregnancies ending in miscarriage. From our viewpoint we may consider that miscarriage or abortion is exactly the same as a pregnancy as far as the breast is concerned. It hypertrophies and produces milk.

The above is a definitely higher figure for miscarriage than that of the average normal. There are no accurate figures available on studies relating to miscarriage and abortion either in the average normal American woman, or in those having definite pathology relating to the pelvis. Every author admits there are no exact studies on this point, then proceeds to estimate what he thinks the figures would be.

Titus¹⁰ in a study of the cases at the Johns Hopkins Hospital stated that 1 to 171/3 obstetrical cases ended in miscarriage (5.76 per cent). This figure is in striking contrast to our mammary cancer cases having 31 per cent ending in miscarriage or abortion.

¹⁰ Titus: Am. Jour. Obst., Vol. 65, p. 960.

Hall¹¹ quotes Hagre as giving one miscarriage to every 8 to 10 labors, and Whitehead in England as one miscarriage to every seven labors.

Williams¹² stated that in his service between 8 and 10 per cent ended in abortion or miscarriage, that is, one in every ten or twelve.

ONE HUNDRED CONTROL CASES

In making my study of the 100 control cases having no cancer, in order to compare with the 200 mammary cancer cases, no case was included under thirty-five years of age. These 100 cases could be considered normal American women. Their condition was either entirely normal, or they were under treatment for some condition other than mammary or pelvic. In order to get a more exact cross section of population, one-half were private cases and the other half were clinic patients.

In the study of the 100 cases one is struck by the complete lack of unusual incidents relating to the nursing history and to such incidents as abscess formation, inverted nipples, caked breasts, miscarriage, etc. The children were nursed for the normal period (six to nine months) without complications. This is in marked contrast with the cancer cases where these complications were such prominent and common features.

Of the 100 patients, 78 had borne 123 children; and there were only 18 miscarriages or abortions, which is one miscarriage to seven labors. This fits rather well into the impressions of Williams (1 in 10), Hagre (1 in 9) and Whitehead (1 in 7). In the cancer cases there was one miscarriage to every three labors. Therefore, there is a striking difference in the incidence of miscarriage of the control and the cancer cases, one being more than double the incidence of the other. This figure has an important bearing on the relationship of miscarriage to mammary cancer. Several factors of stagnation may be present in the same patient. This we found to be true in many instances; as an example, an inverted nipple may be present in a patient who has had three children and nursed but one of them; this same patient may have also had a miscarriage. The inverted nipple, the lack of nursing and the miscarriage make three factors dealing with impaired drainage.

In all probability, the most important part of the studies on drainage and stagnation was the work of Dr. Halsey Bagg of our Research Laboratory. It especially adds to the above clinical studies because he was able to artificially produce stagnation in animals and as a result, produce mammary cancer. Female mice¹³ were "selected from a strain of animals with a well-known low rate of tumor incidence. Less than 5 per cent of females from this strain

produce mammary carcinoma when allowed to breed normally, and cancer of the breast does not appear in this small percentage until the animals are between one and a half and two years of age. Test animals from the above group were bred when very young and their litters removed immediately after birth and the mothers remated at the estrus that promptly follows parturition. In a second group various combinations were made of periods of suckling of one litter and non-suckling of the next litter, etc. In a third group mammary ducts were ligated at the nipples on one side of the body in order to produce artificial stasis of the mammary ducts. These animals were allowed to breed and suckle their young. Mammary cancers have developed in these animals by the various methods described.

"The clinical observations above are in line with laboratory experiments, wherein animals were allowed to breed very rapidly but were prevented from nursing their young. The females developed mammary carcinoma at a comparatively early age, and a histological study of their breast tissues showed a pronounced dilatation of the mammary ducts, which were filled with stagnating milk. The tumors were definitely malignant, grew rapidly, appeared at multiple foci, recurred after operation, and eventually killed their hosts. In a group of 15 animals, in which a condition of breast stagnation was produced by nontraumatic means, 13 females, or 87 per cent, developed mammary carcinoma. It was also found that when periods of suckling alternated with periods of non-suckling, cancer of the breast appeared in these animals after fewer consecutive pregnancies as compared with females that had had many litters, but had been prevented from nursing any of them. In the non-nursing group, prevention of suckling resulted in lack of normal development of the entire breast system; while in the other group there were periods at which the breasts were allowed to reach their normal limit of growth. It was in the latter group that cancer appeared after fewer consecutive litters.

"The ligation of mammary ducts in animals has been followed by carcinoma of the breast. This group of animals so far comprises few individuals, but, nevertheless, it is interesting to note that in the first animals tested, two of the operated females developed mammary tumors on the side of the body on which the ducts had been ligated. Histological examination showed them to be malignant, solid, mammary carcinoma associated with marked stagnation of the duct system on the ligated side of the body."

In the light of the foregoing studies of the 200 cancer cases, the 100 control cases and the experimental evidence, it strongly suggests that mammary cancer results from abnormal lactation and stagnation. The implication to clinicians is that normal nursing of infants for a normal period should be adhered to unless there are definite contra-indications.

SUMMARY

A clinical study is made of 200 consecutive cases of cancer of the breast, particularly with

¹¹ Hall: Am. Jour. Obst., Vol. 55, p. 72.

¹² Williams, J. W.: Obstetrics. Appleton, 1931, p. 1157.

the idea of evaluating the various factors of breast drainage and stagnation. The stagnation theory of cancer development is explained. Consideration is given to such factors as caked breast, abscess of the breast, nipple trouble (tenderness and cracked nipple), nipple inversion, the presence of cysts, benign tumors and inflammatory lesions, miscarriages, etc. The functional activity of the breast is considered. Chemical analysis is made of the fluid and creamy material extracted from the breast by pumping. In these fluids are found both lactic and butyric acids. These acids are considered to be an important part of those irritating factors responsible for the tissue reactions resulting in hypertrophy, precancerous changes and eventually cancer. The breasts are pumped in order to abolish localized mastitis.

Only 8.5 per cent of the cases which developed mammary carcinoma gave a normal nursing history; or a history entirely free from the various developmental or accidental incidents leading to at least one and sometimes two, three, or more of the various factors causing impaired drainage. In this cancer group every third pregnancy ended in miscarriage or abortion, while in the control cases of 100 normal women, there was only one mis-

carriage or abortion for every 7 pregnancies. Twenty per cent of the cancer women bearing children nursed only a part of the children; 16 per cent did not nurse their children at all. Of the 78 mothers in the 100 control cases, 62, or 80 per cent, gave a normal history of nursing. This figure is in marked contrast to the figure of 8.5 per cent referred to in the foregoing, giving a normal nursing history in the cancer cases.

The clinical studies seem to fit the experimental studies of Bagg who produced artificial stagnation by breeding experiments and by ligating the nipples of the breasts. He found that his particular strain of laboratory mice spontaneously developed mammary cancer in 5 per cent of his animals; but under the influence of artificial stagnation he got as high as 87 per cent development of mammary cancer. The combined study of events in the 200 cancer cases, with the 100 normal control cases, fits well into the general scheme of the experimental production of mammary cancer. The theory although as yet unproven in the human, points out the various factors in the causation of mammary cancer; it also implies as a corollary, that the human should nurse her child unless there is some definite contraindication.

QUACKERY FLOURISHING IN THE DEPRESSION

While legitimate practitioners are hard hit by the business slump, the quacks enjoy an era of prosperity. "During such periods the tendency to establish unsound and dangerous methods of administering medical care is greatest," says Dr. R. G. Leland, Director of the Bureau of Medical Economics of the A. M. A.

An illustration of this is seen in Missouri, where the State Medical Association and the State Board of Health are uniting in a systematic attack on cancer quacks and false cancer cures. Two St. Louis doctors (not members of the Association) have been assessed heavy damages for treating a patient for so-called cancer by the application of a "paste." The case was tried before a jury, and the verdict, as reported in the Journal of the State Association, was unanimous. Several members testified that the paste was a futile effort to cure real cancer, though it might cure certain kinds of noncancerous tumors and sores. The tragic effects of this sort of treatment of true cancer, by delaying scientific treatment beyond the time when such treatment would cure the disease, was made plain to both the court and

what a frightful waste of life was wrought by such quackery and warned the public against medical fakirs.

The Missouri plan of campaign against quacks is interesting. It involves the cooperation of the State Board of Health, the State Medical Association, the local committee of the American Society for the Control of Cancer and the press to educate the people on the early symptoms of cancer and the necessity for consulting only reputable physicians who have the indorsement of the State Medical Association. As a preliminary movement the American Society for the Control of Cancer will conduct a survey of the state which will include not only collection of statistics on cancer fakirs and their unhappy victims but also make a thorough observation on all phases of cancer problems in Missouri. The results of this survey will enable the State Board of Health and co-operative agencies to establish a far-reaching campaign of public instruction that should and undoubtedly will cause cancer sufferers and those who think they have cancer to pause before allowing a self-advertised "cancer-specialist" to treat him and lead

Putting Common Sense Into Workmen's Compensation

Certain abuses that have crept into the administration of the Workmen's Compensation Law are to be corrected, it is hoped, by drastic amendments proposed by the committee of ten physicians which has had the matter under consideration for nearly a year. They say that the present law has failed to protect the injured workmen against "notorious racketeer rings," and the amendments aim to give them full protection from that sort of rascality. No one who scans the suggested changes in the law can deny that they are filled with the spirit of common sense. That is what every law should be, of course, "codified common sense," and the proposals of the committee should go a long way toward righting the evils that have been the cause of complaint.

For example, the committee recommended that physicians who wish to enroll for compensation work must register their qualifications with the County Medical Society where they reside, and that the medical society or its board shall certify to the industrial commissioner the character of medical service the applicants are qualified to render. The commissioner shall then issue certificates of enrollment to the physicians sponsored by the county medical society, and the society may, if necessary, recommend the removal from the roll of "a physician whom it finds guilty of a breach of professional or ethical conduct, malpractice, professional incompetence, or any infraction of the provisions of this act."

What is more, the county medical societies are to be responsible for inspection of the compensation medical bureaus or clinics, and will make recommendations concerning the licensing of them. In this way responsibility "will be delegated in large part to the organized medical profession," as of course it should be.

Medical fees, says the committee, should be fixed by the commissioner in consultation with the Medical Society of the State of New York and with any other interested parties. "Undercutting, rebating, splitting or refunding of medical fees will be eliminated by making such practices illegal."

Another piece of common sense appears in the advice that "all obscure or difficult questions involving medical facts should be decided by physicians and not by lay judges," their decision upon the facts to be conclusive. It is also recommended that at least one member of the industrial board should be a physician.

Even if all its recommendations should be adopted, the committee advises that the operations of the new law be watched by a committee for two years "with a view to recommending correction of faults which may be revealed by subsequent experience."

There is not space here even to mention all the points in the report, or to go over the pros and cons of the disputed recommendation that injured workmen shall have the right to select their own physicians. The progress of the new legislation will be watched with the deepest concern by the many physicians in this state who wish to see our workman's compensation service raised to the highest plane of efficiency and justice, both to the victims of industrial injury and to the physicians who restore them to health and usefulness.

Economics

Before the period of depression the belief of the average man was, that the theory of economics is largely confined to college courses, and the practical application to some government departments, large financial corporations, and collectors of industrial statistics. The same term has often dignified the relatively dilettante activities of smaller groups whose efforts were to search for remedies to control larger or smaller evils, now and then imaginary. The feeling was general that an economic survey would result in an obvious remedy if the task were properly done.

As the present period of financial stress became drawn out and people in all walks of life were affected by it to a greater or lesser

extent, the demand for economic studies of many conditions has become more insistent, with the hope that remedies will thus be made obvious. This trend affected the federal government in like manner, and in consequence such men as Irving Fisher, J. M. Keynes, George F. Warren, and Professor Cassel, all economists of unusual prominence, have been put to work on national finance. As a result, Cassel wishes a fixed gold standard with a control on the volume of credit, Fisher wishes a fluctuating gold content of the paper dollar, Keynes wishes a fluctuating value of gold itself, and Warren has not yet decided just what plan he considers best, but in the meantime it is said, puts the price of gold on a slip of paper each morning. The object of this review is not to criticize the effort but simply to show how a group of outstanding economic specialists are not only unable to agree on the matter of procedure but also have little in convincing arguments on the ultimate success or failure of the remedy.

Walter Lippmann recently said in the *Herald Tribune*, the belief that overproduction with consequent excess of everything, goods as well as human service, were the cause of depression, is an optical illusion; that in fact these are the result and not the cause, and difficult as it may be to believe, the proof can be found in economic history. Thus it is quite evident first, that most efficient economic study does not necessarily put a finger on the cause of an evil, and second, that such study does not necessarily prompt a remedy for the evil.

Financial stress more than all else is also the reason for the increasingly insistent demand for research in medical economics. County societies, state societies and the national bodies are besieged with demands from members to activate committees on economics and to devote medical meetings to the subject. Inaugural and valedictory addresses by the presidents of these societies are now mainly learned discourses on trends in medicine, economic status, and defense against real or imaginary spectres near-by or remote. Committees on economics vie with one another in their assiduous search for the malady and the remedy. The Committee on Economics of our Society compiled a classic report in 1932 of 163 items with 93 references to the literature, all on 20 closely printed pages of this JOURNAL. It was a detailed account demonstrating the complexity of the situation and the fact that no one remedy can cure the many evils. Still the demand is not satisfied, as well shown in a recent copy of the *Medical Alliance Review*, which states: "A new civilization is evolving under our eyes. We do

nothing. In its characteristic and cumbersome way, the County Society has yielded as much as it can. In the face of movement that is too bewildering, change that is too rapid, it stops dead in its tracks." In the same copy follow brief articles by Charles Gordon Heyd and Samuel J. Kopetzky clearly indicating the impending changes in the practice of medicine and the manner in which these may be met for the best interests of the profession as a whole.

While it is apparent that collectivism in one form or another has to a considerable extent already and is still further succeeding individual effort, in the main this applies largely to the prominent urban centres of our country which are after all but a minor part of the whole.

With no desire to belittle the influences which have and are still bringing about changes in medical practice, nor to detract from the significance and merit of proper study of these by men qualified for this work and the benefits these may achieve for the individual physician or the entire profession, nevertheless individual success remains as before the result of individual effort. No amount of economic study and no extent of solutions of existing evils determined in this way, will at the moment avail the individual who expects his medical society or the government to improve his status. Personal incentive to find a proper place in the existing order of things and to rise according to merit, always was and still is the method of success. This is done by knowledge and work and not by demands on a committee of economics or the cry to them for relief from existing evils.

A recent number of our JOURNAL refers to an extract from an article by Walter Lippmann so relevant and so true that a complete repetition is ventured. "I do not think it is possible to find an instance where a social order has been radically altered because someone thought some other kind of order would be better. There has to be a complete breakdown of the old order, a total paralysis, and an extinction of all hope that it can revive, before a genuine social revolution occurs. When these conditions do not exist, you may get a change of government, in moments of excitement even a violent change, but when the smoke clears away, you are pretty sure to find the essential institutions and habits of the nation the same." The true family doctor has for all time been the servant, counselor and friend of man. The social order may be upset and all men made equal thereby, but individual incentive will again lead to mastery in the final analysis of any scheme, and the

individual physician will again be servant, counsellor and friend.

not have any technocracy in medicine. Keep the man first, where he belongs.

The Man Must Always Come First

When we analyze the instinctive feeling that surges up in every doctor's heart in opposition to state medicine, we can find pretty generally that he resents it because it is an attempt to put the institution above the man. Medicine is preeminently a calling where the man must always come first.

In a way, of course, this is true of all callings, true of all real progress. "The problems of the future will grow out of the present tendency to substitute the institution for the man," said a teacher in Alabama who had worked 20 years for a power company and then decided to go back to his old profession. "I have examined some 15 to 18 of the outstanding experiments throughout the world," he added, "attempts to substitute the institution for the man, and I can defend with success on any platform in America the thesis that in every case civilization has continued to grow only so long as the institution has been subordinated to the man. Our problem then is to return to that fine individualism in which man is paramount to the institution."

The relation between doctor and patient is one that can be institutionalized, it is true, but only to bring it down to a lower plane, only to rob it of its best qualities. There is no disputing the fact, of course, that we are living in a machine age and that a thousand things formerly made by hand are now turned out better by machinery. We even hear of churches with radio loud-speakers in the pulpit. But we have yet to hear of a dying church member who wanted a radio apparatus to hold his hand or a mother who wished her baby baptized by a gramophone. In life's critical and vital hours we want the human touch. When illness strikes down the father or mother or threatens the life of a little child, the family physician is the one who is wanted. Medical skill is needed, but something more is demanded too—the man behind the skill. It is just that impalpable something that cannot be supplied by any state institution or system. With it we have the splendid service that has made the old family doctor the hero of song and story. Without it we have a machine made system with all the efficiency of a Ford factory, perhaps, but lacking the human touch, the warm heart-beat, the sympathy that fills the patient with a new vigor and "doeth good like medicine." Not long ago we were all "steamed up" over the perils of technocracy, the domination of the machine. Let us

Certification of Specialists

The rapid multiplication of specialists and the over-emphasis on specialization in medical practice have been due to several factors, not the least of which is that the public began asking who is a specialist before it thought to inquire what a specialist is. In view of the disproportionate number of teaching hours devoted to the specialties by the undergraduate schools, and the fact that the emoluments of an expert in one of the branches of medicine are usually greater than those of a general practitioner, it is not surprising that certain men have become specialists by pronouncement.

The term "specialist" implies that the physician so designated has had intensive training and wide experience in the field to which he limits his practice. The public, lay and medical, are entitled to know what particular qualifications he possesses and by what authority he classifies himself as such. The people at large also have a right to expect that the medical profession will safeguard them from the practices of pseudo specialists. The previously existing uncontrolled status of specialism could not have continued indefinitely. It was imperative that the medical profession fix the requirements for legitimate specialization and provide an acceptable plan for putting the stamp of approval on well qualified specialists. Otherwise the self-anointed reformers outside the profession might have devised drastic regulations to hamper organized medicine still further.

The American Board for Ophthalmic Examinations began to function in 1917, the American Board of Oto-Laryngology in 1926, the American Board of Obstetrics and Gynecology in 1930, and the American Board of Dermatology and Syphilology in 1932. Collectively, these boards have now examined and certified to the proficiency of nearly four thousand specialists. They are all endowed with an unassailable prestige, having been organized in each instance by the special National Societies and the corresponding Sections of the American Medical Association. At the present time groups of urologists, orthopedic surgeons, gastroenterologists, proctologists, pathologists, and pediatricians are considering plans for the creation of similar Boards. The objectives of all such examining Boards are educational and constructive, not legislative or restrictive. Their activities are devoted chiefly to encouraging and inducing potential specialists to prepare themselves thoroughly, to persuading

hospitals to provide adequate facilities for special training, to conducting examinations designed to test the qualifications of voluntary candidates for certification, and to granting certificates of proficiency to qualified applicants. The Boards are composed of elected representatives of the National Societies, personal favoritism and prejudice are completely eliminated, and the character of the examinations is such that no candidate need anticipate the slightest embarrassment.

Several of the National Societies have already made the possession of one of these certificates essential for membership, and some hospitals are accepting them as a standard for evaluating the capabilities of their staff members. What was originally a timid experiment has now become an irresistible movement, and the day of the incompetent self-styled specialist is numbered. There need be no fear of mushroom Boards, organized by independent groups. They could not survive the expense involved in their operation. It can be the function of the American Medical Association to certify the authenticity of the Boards; it is the business of the Boards to certify the specialists.

Dr. Linsly Rudd Williams

A Tribute

THE passing of a physician who has stamped his work and his personality upon the community to an extent that calls forth the laudatory comment which has appeared in the lay press at the death of Dr. Linsly Williams is an event worthy of close attention by the medical profession. It is worth while that we should pause in our busy lives to study the career of such a man.

Dr. Williams received the usual educational training that pertains to all doctors. He spent his undergraduate years at Princeton University and then received his degree of Doctor of Medicine from the College of Physicians and Surgeons at Columbia University.

His internship at the Presbyterian Hospital brought him in contact with a group of men actively engaged in the practice of medicine and also interested in matters of education and public health. From these sources he received an impress which continued throughout his life.

As a practitioner, he proved himself capable, fine, helpful, and wise. He found in this field a peculiar delight and the clientele that he built up at that time remained his devoted friends.

He was blessed with wide vision and an urge to accomplishment. As the years progressed, he looked more and more upon the broader aspects of all that pertained to the healing of the sick. He associated himself with those who were like-minded. He was one of that small group who in 1911 organized the first formal activity of the New York

Academy of Medicine in public health under the able leadership of Dr. Charles L. Dana. Even during his absences from the city, Dr. Williams never lost contact with this group and in the last year of his life his work with the Committee on Public Health Relations of the Academy was among his major activities. So great was his success in this field that he attracted attention in many directions and became so strong a factor that when Dr. Herman Biggs under the revised health law became the first Commissioner of Health, in the State of New York, he turned to Dr. Williams for his first Deputy. During the years in which he served in this capacity, he became fully informed of the problems not only of public health in the State of New York, but those of medical education and private practice. He was known as a health officer of unusually fine perception and constructive ideas.

He terminated this service in order to fulfill what he considered his obligation in a larger field by going to France during the War. There as an army medical officer he proved his ability to meet any and all demands. A letter written during his last illness by a German, touchingly testifies to the debt of Germany for the work he did among German civilians while he was serving with the army of occupation in the sanitary corps. What he did there was of such an outstanding nature that he was called upon to remain for several years after the close of the War in order to help France in solving her problem connected with the tragedy of tuberculosis.

His interest and knowledge in medical educational matters were recognized by Columbia University where he was elected to the Board of Trustees, a position which he occupied for several years.

A review of this training and experience indicates that he was possessed of an unusual range of interests and abilities.

One of the conditions upon which the New York Academy of Medicine was enabled to obtain the necessary funds to move to its present home at 103rd Street and Fifth Avenue was that its affairs should be managed by a permanent, full-time, Director under the Trustees and Council. The Academy and the community, if not the nation, is the debtor of those who knew Linsly Williams and recognized in him the ideal person for this office. The varied training already cited made him a perfect administrator for such an undertaking. He knew the problems of the private practitioner. He had definite ideas concerning medical education based upon careful observation. He was a qualified expert in the field of public health and he possessed the intellectual vigor to weld these various phases into one coordinating whole.

During the exactly ten years that he guided the affairs of the Academy, he was a leader in the best sense of the word. No officer of the Academy is unaware of the fact that no matter what devotion and energy he may have

applied to his office, the leadership was always in the hands of Dr. Williams and it was rare indeed that any project toward progress was approached without its being learned that the Director had already formulated plans concerning it.

Under this influence, the Academy has come to be recognized as holding a unique position not only in its own community, but throughout the state, the country and even abroad. Dr. William H. Welch has repeatedly stated that it has no duplicate in the peculiar quality of service which it renders throughout the world. This is the monument that stands to the name of Linsly Williams.

His abundant energy would not permit him to confine his service solely to the field of medicine. He was a valued advisor to city, state, and national officials.

When the evils connected with the Veterans Bureau were brought to his attention, he devoted an enormous number of his already overcrowded hours toward aiding in the correction of these evils. He was prominent in all constructive action connected with the National Economy League in this particular endeavor.

It was not by any means solely due to Linsly Williams' education, training, and intellectual equipment that he was able to make such a great impress upon the life of his time. He possessed a genius for companionship and friendship. A clear thinker, a constructive organizer, he was more often than not sparing of his words in any discussion where controversial matters were at issue. Those who worked closely with him will remember the constant experience of having him sit quietly and listen to various opinions advanced, often with an approach of serious

opposing views, without contributing to the discussion. At the end, a short, succinct, definite statement from him would sum up the essentials of the entire matter and formulate a line of action enthusiastically accepted by all.

The many knotty problems which were brought to him arising out of that most difficult of human relations, clashes in personalities, were always handled with the skill of a true statesman, a name which was applied to him by the writer of one of the lay press editorials. He possessed that fine sense of humor which could always take the sting out of disturbing differences of opinion and bring the contestants into hearty accord. He never moved in any direction because of expediency. He formulated his policies after careful study. He asked cooperation to put them into effect and if he found that the time was not ripe for such a move, he waited for a more opportune day.

Were the material available, someone could render a real service in writing the biography of Linsly Williams showing the man as he was. The outstanding factors in his career, the end of which has left such an impress of bewildering loss upon us all, were a sound training for accumulating experience, a thoughtful, constructive utilization of experience for further progress, an unswerving adherence to principle, a kindly sense of humor, a strong tactful use of his abilities and a determination that he would devote such talents as a kindly Providence had bestowed upon him, to make the world in which he lived a brighter and happier one. In this thought lies the heart of the lesson which we may get from the life of our friend, Linsly Rudd Williams.

JOHN A. HARTWELL, M.D.

The Annual Meeting of the State Society

THE next Annual Meeting of the Medical Society of the State of New York will be held in Utica on May 14th, 15th and 16th. There are many reasons why you should make a special effort to attend this meeting. There will be a discussion of your social relations, a practical presentation of scientific papers and an opportunity to meet with your fellow practitioners. At the Annual Meeting you will become rejuvenated and again enthusiastic about your life work.

Your Society is carrying on an immense work. Plan to visit the legislative body, the House of Delegates, as they deliberate over the vital problems concerning organized medicine. The delegates assemble on the 14th floor for an afternoon and evening session and again on the morning of the 15th.

Decide to enjoy and profit by the various

scientific presentations selected for you by Dr. William A. Groat of Syracuse, the Chairman of the Committee on Scientific Work, and his competent assistants, the chairmen of the various Sections. Papers will be read on the 15th and 16th.

There will be a Scientific Exhibit under the direct supervision of Dr. William F. Jacobs of Buffalo. Those of you who have visited previous Scientific Exhibits know their great value and we urge all who have not so profited to prepare their schedule so that they may have plenty of time to make a critical inspection of the numerous demonstrations which will be arranged for them at the next Annual Meeting.

The Chairman of the Committee on Arrangements, Dr. Andrew Sloan of Utica, has selected an active committee and you are assured of physical comfort during your stay in Utica.

Plan to be in Utica May 14th, 15th and 16th.

Society News

Report of the Committee on Workmen's Compensation

APPOINTED BY HIS EXCELLENCY,
THE HONORABLE GOVERNOR HERBERT H. LEHMAN

THE present Workmen's Compensation law is designed to protect the working man, when injured, by shifting part of the burden of industrial accidents from the industrial worker, who cannot support it, to the industry, which can bear the financial strain. At the same time it serves to protect the employers of labor from the burdens and occasional inequitable decisions of civil suits. Essentially, the present law requires the employer to provide prompt medical treatment for an injured employee for whatever period the injury demands and to pay him compensation for the duration of any disability lasting more than seven days.

The law has not worked to the benefit of the working man as well as had been anticipated. He often fails to obtain adequate medical care. Racketeering has become notorious. Unscrupulous and inefficient industrial clinics, not infrequently controlled by laymen or unethical physicians, are able to conspire within the law with unscrupulous employers and insurance carriers to obtain for themselves, by means of rebates, the privilege of treating injured workmen. Medical service rendered under these circumstances is usually inferior. In order to secure additional income and to cover the cost of the rebate or commission, treatment has been needlessly prolonged and bills for medical services have been excessive. The cost of insurance to the honest employer has been thereby increased and insurance carriers have been unable to estimate accurately the actuarial risk so that they have lost money on Workmen's Compensation insurance.

The abuses which have resulted under the present law may be subdivided into those over which the medical profession has at present no control and those directly attributable to the medical profession.

Abuses over which the medical profession has at present no control.

1. The hiring of cheap and incompetent medical service by employers and insurance carriers. This was one of the important disclosures of the Committee on Workmen's Compensation appointed by former Governor Roosevelt. The practice of cutting the rates for medical service below a reasonable minimum figure is indulged in by some of the insurance companies, commercial clinics, and even by the State Insurance Fund. The effort to secure the cheapest possible medical

service has been responsible for such medical incompetence, padding of bills, prolongation of treatments and rebating.

2. Reduced charges by hospitals in order to obtain cases.

Hospitals which accept compensation cases at a per diem rate which is less than the actual cost of hospitalization meet the loss by diverting funds which have been given for philanthropic purposes.

3. "Lifting."

Lifting of cases during the course of treatment has been practiced by some insurance companies and self insurers, in order to transfer the patient to a cheaper or more favored physician or hospital and, not infrequently, in order to secure more favorable testimony at subsequent hearings before the Department of Labor. Not only ambulatory patients but also those hospitalized in competent hospitals have been transferred at considerable risk to the patient.

4. Errors in causal relationship.

- a. Carriers have frequently attempted to prove wrongly that patients were malingering or that the injury did not result from their occupation. This injustice has been most flagrant when carriers have been direct employers of the physicians.
- b. In occasional instances, diseases which have occurred three or more years after an injury have been wrongly attributed to the injury or occupation. Awards have been made by lay referees for tuberculosis, senile conditions, cardiorenal disease, neurological conditions, and cancer, which had no relationship to the antecedent injury or occupation.
- c. The ultimate decision concerning causal relationship and compensation is made by a lay referee listening to opposing medical testimony of experts employed by the interested parties. He must evaluate this highly technical evidence without sufficient knowledge, and, as a result, injustices frequently occur. These errors are especially frequent in the fields of specialization—particularly the eye, ear and central nervous system. Unjust decisions are also common in cases of death or total disability.

5. Postponement of compensation awards.

Frequent delays occur both in the hearing of cases and in the granting of compensation,

even when the injured working man is in financial distress.

6. Other legal injustices.

The injured workman who believes that he has not received proper medical treatment or a fair award of compensation is placed in an unfair position by the fact that his most important witness, the physician who has treated him, is engaged and is paid by the employer or insurance carrier. Also, the medical records are in the possession of the employer or carrier, who can afford to be represented by counsel and by paid medical experts. The impartial attitude of the referee does not compensate the injured workman for these disadvantages.

Abuses due to the medical profession.

1. Inefficient medical treatment.

Despite the fact that the majority of injuries are of minor nature and can be treated competently by the general practitioner, severely injured working men who should have been referred to a surgeon or specialist have at times been treated by physicians insufficiently trained in traumatic surgery.

2. Over-treatment and over-charging.

Some physicians have seen patients more frequently than the injury required, and have rendered bills which were much higher than the treatment warranted.

3. Prolongation of period of compensation.

Physicians have occasionally conspired with the injured working man to obtain compensation for him for a longer period than his injury warranted.

4. Prolonged physical therapy.

Treatment is commonly given without medical supervision by untrained nurses or assistants. It is often unnecessarily prolonged. The working man is delayed from returning to his normal occupation, and compensation as well as medical costs are thereby increased.

5. Inadequate medical testimony.

Cases are too often postponed without medical testimony having been taken. This is due to the fact that physicians are often subpoenaed to testify at compensation hearings without remuneration and at times that interfere with their professional work. Moreover, they are often resentful and their testimony is therefore perfunctory and inadequate.

6. Medical advertising and racketeering in order to secure cases.

These practices are resorted to by some unethical physicians and compensation clinics controlled by laymen or by unscrupulous physicians. We shall refer to such clinics as Compensation Medical Bureaus.

The following excerpts are from the report of Frances Perkins, former industrial commissioner of the State of New York:

"Conspicuous is the practice of intensive solicitation for the 'business' of treating claimants. Many clinics employ advertising distributors to canvass employers and post on the employers' premises cards that are obviously designed to convey some official

connection with the 'workmen's compensation.' In addition, some of the clinics offer employers first-aid kits as an inducement for patronage.

"Competitive rivalry between clinics frequently results in attempted 'lifting' of cases and there is indication that this competition is carried on even to the extent of offering inducements to the injured claimants.

"Some of the clinics are inadequately equipped and are maintained in a slovenly manner.

"Many, especially those of the chain variety, are staffed by low-salaried physicians and by so-called 'nurses' with little or no training. Instances have been shown where these non-professional attendants actually give treatments and so forth in the absence of the physician though, perhaps, legally under the latter's direction.

"There is reason to believe that in numerous instances treatments are prolonged for the sole benefit of the clinics, although claimants may benefit through certification of disability by the clinic.

"Some of the facts develop the possibility of connivance between employers and clinics whereby the latter may return in some form and extend a part of the money collected from carriers through treatment of injured cases."

These and other abuses of the law have been repeatedly revealed by committees of the Labor Department, the Bar Association, the Special Committee on Workmen's Compensation appointed by former Governor Roosevelt, and they have been confirmed by the investigations of this committee. We therefore recommend that the Workmen's Compensation Law be revised in the following respects in the interests of the injured workmen, the conscientious employer of labor, the insurance carriers, and the medical profession.

Recommendations

Recommendations 1 to 6 are designed to regulate medical practice under this act so as to provide more adequate medical and surgical care for the injured workmen and to eliminate the many evils of the present law. Recommendations 7 and 8 define the medical activities of the insurance carriers. Recommendations 8 to 12 are concerned with improvements in compensation procedure.

Accompanying this report is a tentative draft of the revised provisions of the Workmen's Compensation Act, as proposed by this Committee.

1. Limited Free Choice of Physician by the Employee.

It is the opinion of your Committee that the principal abuses as they affect the workmen are due primarily to the manner in which medical service is at present provided, and that they can be corrected only by granting the injured workman the right to choose a

Society News

Report of the Committee on Workmen's Compensation

APPOINTED BY HIS EXCELLENCY,
THE HONORABLE GOVERNOR HERBERT H. LEHMAN

THE present Workmen's Compensation law is designed to protect the working man, when injured, by shifting part of the burden of industrial accidents from the industrial worker, who cannot support it, to the industry, which can bear the financial strain. At the same time it serves to protect the employers of labor from the burdens and occasional inequitable decisions of civil suits. Essentially, the present law requires the employer to provide prompt medical treatment for an injured employee for whatever period the injury demands and to pay him compensation for the duration of any disability lasting more than seven days.

The law has not worked to the benefit of the working man as well as had been anticipated. He often fails to obtain adequate medical care. Racketeering has become notorious. Unscrupulous and inefficient industrial clinics, not infrequently controlled by laymen or unethical physicians, are able to conspire within the law with unscrupulous employers and insurance carriers to obtain for themselves, by means of rebates, the privilege of treating injured workmen. Medical service rendered under these circumstances is usually inferior. In order to secure additional income and to cover the cost of the rebate or commission, treatment has been needlessly prolonged and bills for medical services have been excessive. The cost of insurance to the honest employer has been thereby increased and insurance carriers have been unable to estimate accurately the actuarial risk so that they have lost money on Workmen's Compensation insurance.

The abuses which have resulted under the present law may be subdivided into those over which the medical profession has at present no control and those directly attributable to the medical profession.

Abuses over which the medical profession has at present no control.

1. The hiring of cheap and incompetent medical service by employers and insurance carriers. This was one of the important disclosures of the Committee on Workmen's Compensation appointed by former Governor Roosevelt. The practice of cutting the rates for medical service below a reasonable minimum figure is indulged in by some of the insurance companies, commercial clinics, and even by the State Insurance Fund. The effort to secure the cheapest possible medical

service has been responsible for such medical incompetence, padding of bills, prolongation of treatments and rebating.

2. Reduced charges by hospitals in order to obtain cases.

Hospitals which accept compensation cases at a per diem rate which is less than the actual cost of hospitalization meet the loss by diverting funds which have been given for philanthropic purposes.

3. "Lifting."

Lifting of cases during the course of treatment has been practiced by some insurance companies and self insurers, in order to transfer the patient to a cheaper or more favored physician or hospital and, not infrequently, in order to secure more favorable testimony at subsequent hearings before the Department of Labor. Not only ambulatory patients but also those hospitalized in competent hospitals have been transferred at considerable risk to the patient.

4. Errors in causal relationship.

a. Carriers have frequently attempted to prove wrongly that patients were malingering or that the injury did not result from their occupation. This injustice has been most flagrant when carriers have been direct employers of the physicians.

b. In occasional instances, diseases which have occurred three or more years after an injury have been wrongly attributed to the injury or occupation. Awards have been made by lay referees for tuberculosis, senile conditions, cardiorenal disease, neurological conditions, and cancer, which had no relationship to the antecedent injury or occupation.

c. The ultimate decision concerning causal relationship and compensation is made by a lay referee listening to opposing medical testimony of experts employed by the interested parties. He must evaluate this highly technical evidence without sufficient knowledge, and, as a result, injustices frequently occur. These errors are especially frequent in the fields of specialization—particularly the eye, ear and central nervous system. Unjust decisions are also common in cases of death or total disability.

5. Postponement of compensation awards.

Frequent delays occur both in the hearing of cases and in the granting of compensation,

for injuries and illnesses arising out of industry, except for emergencies.

Infractions of the education law will be referred by a county medical society or by the commissioner to the Committee on Grievances, constituted under 51265 of the Education Law.

The county medical societies or boards designated by them are also to be responsible for inspection of compensation medical bureaus (formerly called compensation clinics) and for making recommendations to the commissioner concerning the licensing of these medical bureaus.

In this manner, the responsibility for maintaining proper standards of professional conduct and professional competence will be delegated in large part to the organized medical profession. The injured workman will be limited in his choice to physicians capable of treating him for his particular disability, the employers and insurance carriers will be protected against professional abuses, and unscrupulous or incompetent clinics will be eradicated.

5. Standardization of Medical Fees.

Medical fees for various types of industrial accidents and illnesses are to be fixed for the State by the commissioner, after he has requested the Medical Society of the State of New York to submit a schedule of fees which it deems fair and adequate and has given other interested parties an opportunity to express their views. These fees are to apply as minimums to all physicians treating compensation cases, whether chosen by the employee or by the employer. A similar schedule of medical fees was established in New York City within the past two years by agreement between the National Bureau of Casualty and Surety Underwriters and the county societies and has been mutually satisfactory.

Undercutting, rebating, splitting or refunding of medical fees will be eliminated by making such practices illegal. Advertising or soliciting medical work under this act will be punishable as a misdemeanor.

6. Arbitration of Disputed Bills for Medical Services.

Disputed bills for medical services are to be submitted for adjustment to an arbitration committee of four representing the employer or carrier and the physician. A majority vote of the committee is to be conclusive. In the event of equal division, the committee shall choose a single arbiter whose decision will be conclusive.

A similar practice was instituted voluntarily two years ago by the National Bureau of Casualty and Surety Underwriters and the Medical Societies of the Counties of New York, the Bronx and Kings and has been mutually satisfactory. To date about one thousand and contested bills have been referred for arbitration, of which almost five hundred were settled by mutual agreement before the hearing. Every one of the remaining five hundred cases were settled by unanimous agreement of

the arbitration committee and the decision was accepted by both parties in all but one instance.

7. Elimination of Medical Practice by Insurance Carriers.

The investigation indicates that some insurance carriers and even the State Insurance Fund have been guilty of the practice of attempting to provide unduly cheap medical care by undercutting and underbidding. Unnecessary lifting of cases and a bureaucratic relationship to injured workmen and physicians have aroused much criticism.

The medical activity of the State Insurance Fund and of all insurance carriers except self insured employers should be limited to the maintenance of a staff of competent medical inspectors to examine compensation cases periodically while under medical or surgical treatment and to report upon the adequacy of the medical care and other matters relative to the medical conduct of the case. It is also recommended that the medical and claims departments of the State Fund and of all insurance carriers be separate.

8. Self-Insurers.

Among large employers of labor who are self-insurers (those who maintain their own medical organization and set up adequate financial reserves under the law to meet disability obligations) the medical care provided for the injured employee is usually good. But abuses exist even among self-insurers. This has been disclosed by the recent revelations involving one of the largest of the self-insurers, the municipality of the City of New York. Furthermore, an injured employee who may have reason to believe that he is not receiving adequate care from a self-insured employer can file a complaint with the Labor Department only at the risk of losing his job. And his chances of proving the inadequacy of medical care are reduced by the fact that the medical records are in the possession of the defendant who can afford to be represented by counsel, and that the most important witness, the physician who treated him, is in the employ of the self-insurer.

Under the proposed amendments to this act, employers who are self-insurers may maintain a licensed compensation bureau but an injured employee is not obligated to use it and may choose his own medical attendant if he desires, subject only to the limitations described in paragraphs 2 and 3 of this report. If the self-insurer maintains an efficient staff, the injured workman will find it advantageous to continue to use the medical service provided by his employer.

9. Determination of Disability.

The lay referees of the Department of Labor now render decisions upon medical matters including causal relationship. Although a medical staff is employed by the labor department, its opinions may be accepted or ignored by the referee. An appeal from his decisions even on medical matters is reviewed

at present by the Industrial Board, all members of which are laymen. The following changes in procedure are therefore provided in the proposed new law.

The primary determination of disability, the degree or percentage of disability and questions of causal relationship will remain the duty of the referees (or the Industrial Board) but when in doubt the referee will have the right to avail himself of the opinion of an impartial expert or, if he disagrees with the decision of the impartial expert, to refer the case for decision on medical grounds to a Medical Advisory and Appeal Board. On all other grounds the appeal will be taken to the Industrial Board.

10. Medical Advisory and Appeal Board.

We urge that all obscure or difficult questions involving medical facts should be decided by physicians and not by lay judges. A Medical Advisory and Appeal Board (or Boards) of three physicians is therefore to be appointed for each compensation district of the State by the industrial commissioner from nine nominations made jointly by the county medical societies of the district. This board is to act upon appeals referred to it by referees or requested by either litigant upon medical facts including causal relationship, the determination of disability and the degree or percentage of disability. The decision of the board upon these facts is to be conclusive. The board may avail itself of the opinion of a qualified impartial expert. Provision is also made for appointment of the Medical Advisory and Appeal Boards by the commissioner in the event that a county medical society should fail to make nominations within a reasonable time.

11. Industrial Board.

As the work of the Industrial Board is to some extent concerned with medical problems, it is recommended that at least one of its members be a physician.

12. Other Changes in Compensation Procedure.

Other changes in procedure include:

1. Punishment for rebating, splitting or refunding of fees and for soliciting or advertising for work, practices which have been responsible for much of the racketeering.

2. Provision for the licensing, inspection and regulation of compensation medical bureaus, previously called compensation clinics.

3. Regulations governing the care of workmen's compensation cases in municipal, county and state hospitals.

4. Regulation requiring a physician to send a preliminary notice to the employer and to the Labor Department within 48 hours after he begins treatment of a case and a more complete report within twenty days thereafter.

5. Regulations expediting hearings before referees and reducing the frequency of postponements.

The Committee is convinced, as were its

predecessors in the investigation of the operation of the workmen's compensation law, that the present law should be altered. The proposed changes in the law which we now submit represent the opinion of the Committee after study of the old law and its operation. The Committee believes that the changes should result in the elimination of many of the faults in the present law. It recommends, however, that a committee be appointed for a period of two years to observe the operation of the revised law with a view to recommending correction of faults which may be revealed by subsequent experience.

Medical Aid Amendments to the Workmen's Compensation Act

Recommended by the Committee

1. (a) The employer shall be liable for the payment of the expenses of medical, surgical, or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus necessitated by the injury of an employee, for such period as the nature of the injury or the process of recovery may require. All fees and other charges for such treatment and services shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living. The commissioner shall prepare a schedule for the State of minimum charges and fees to be determined in accordance with and to be subject to change pursuant to rules promulgated by the commissioner. Before preparing such schedule for the State the commissioner shall request the president of the Medical Society of the State of New York to submit to him a report on the amount of compensation deemed by such society to be fair and adequate for the types of medical care to be rendered under this act, but consideration shall be given to the views of other interested parties. The amounts payable by the employer for such treatment and services shall in no case be less than the fees and charges established by such schedule. Nothing in this schedule, however, shall prevent payment of amounts higher than the fees and charges fixed therein.

- (b) The liability of an employer for the expenses for treatment and services herein provided shall not be affected by the fact that his employee was injured through the fault or negligence of a third party not in the same employ, unless and until notice of election by the employee to sue or the bringing of suit against such third party. The employer shall, however, have an additional cause of action against such third party to recover any amounts paid by him for such treatment or services.

- (c) The referee, the Industrial Board or the Medical Advisory and Appeal Board hearing a claim for compensation may require examination of any claimant by a physician especially qualified with respect to the diagnosis or treatment of the disability for which compensation is claimed; and may require a re-

port from such physician on the diagnosis, proper treatment, or extent of the disability of such claimant. The physician to conduct such examination shall be designated by the commissioner from a panel of especially qualified physicians submitted to him by the medical society of the county. The industrial commissioner shall direct the award for such services.

2. (a) An injured employee may, when care is required, select to treat him any physician authorized by the commissioner to render medical care, as hereafter provided. If the employee is unable or does not desire to select a physician, the employer shall promptly provide him with the necessary medical care.

(b) The commissioner shall prescribe the form of a notice informing employees of their privilege under this section, and such notice shall be posted and maintained by the employer in a conspicuous place or places in and about his place or places of business.

(c) The employer shall have the right to transfer the care of an injured employee from the attending physician, whether chosen originally by the employee or by the employer, to another enrolled physician (1) if the interest of the injured employee necessitates the transfer or (2) if the physician has not been authorized to treat injured employees under this act or (3) if he has not been authorized under this act to treat the particular injury or condition. An enrolled physician from whom the case has been transferred shall have the right of appeal to an arbitration committee as provided in paragraph b of subdivision 7 and if said arbitration committee finds that the transfer was not authorized by this section, said employer shall pay to the physician a sum equal to the total fee earned by the physician to whom the care of the injured employee has been transferred, or such proportion of said fee as the arbitration committee shall deem adequate.

(d) No claim for medical or surgical treatment shall be valid and enforceable, as against such employer, unless within forty-eight hours following the first treatment the physician giving such treatment furnish to the employer and the industrial commissioner a preliminary notice of such injury and treatment, and within twenty days thereafter a more complete report on a form prescribed by the industrial commissioner. The industrial board may excuse the failure to give such notices within the designated periods when it finds it to be in the interest of justice to do so. Upon receipt of the notice herein provided the employer or the carrier shall be entitled to have the claimant examined by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, and refusal by the claimant to submit to such examination at such time or times as may reasonably be necessary to safeguard the interests of the employers or carrier, shall bar the claimant from recovering compensation

for any period during which he has refused to submit to such examination.

(e) No claim for specialist consultations, surgical operations, x-ray examinations, special diagnostic laboratory tests or physiotherapeutic procedures costing more than \$10.00 shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services were required in an emergency in which delay for the purpose of securing authorization might prejudice the patient's chances of recovery or result in an increase in his disability.

3. (a) The commissioner shall upon the recommendation of the medical society of each county or of a board designated by such county society authorize physicians licensed to practice medicine in the state of New York to render medical care under this act. If, within sixty days after the commissioner requests such recommendations, the medical society of any county fails to act, or if there is no such society in a county, the commissioner shall designate a board of three qualified physicians, members of the medical society of the state of New York, who shall make the requested recommendations. No such authorization shall be made in the absence of recommendation of the appropriate society or board. No person shall render medical care under this act without such authorization of the commissioner. Provided, that (1) emergency (first aid) medical care may be rendered under this act by any physician licensed to practice medicine in the state of New York without authorization by the commissioner under this section; and

(2) a licensed physician who is a member of a constituted medical staff of any hospital may render medical care under this act while an injured employee remains a patient in such hospital; and

(3) under the active and personal supervision of an authorized physician medical care may be rendered by a registered nurse, physio-therapist or other person trained in laboratory or diagnostic techniques within the scope of such persons' specialized training and qualifications. This supervision shall be evidenced by signed records of instructions for treatment and signed records of the patient's condition and progress. Reports of such treatment and supervision shall be made by such physician to the commissioner on such forms and at such times as the commissioner may require.

(b) A person licensed to practice medicine in the State of New York who is desirous of being authorized to render medical care under this act, shall file with the medical society in the county in which his office is located or with a board designated by such society or by the commissioner, an application for authorization under this act. In such

shall state his training and qualifications and shall agree to limit his professional activities under this act to such medical care as his experience and training qualify him to render. The medical society or a board designated by it, if it deems such licensed physician duly qualified, shall recommend to the commissioner that such physician be authorized to render medical care under this act, and such recommendation and authorization shall specify the character of the medical care which such physician is qualified and authorized to render under this act. A licensed physician may present to the medical society or board evidences of additional qualifications at any time subsequent to his original application.

(c) Laboratories and bureaus engaged in physiotherapy, x-ray and other diagnostic or therapeutic procedures and which participate in the diagnosis or treatment of injured workmen under this act shall be owned and operated by qualified physicians duly authorized under this act.

4. (a) The medical society or board that has recommended the authorization of physicians to render medical care under this act shall investigate all charges of professional or other misconduct by any authorized physician or by any compensation bureau licensed as hereafter provided, and shall report evidence of such misconduct to the commissioner. Such investigation may be made by the board of an adjoining county upon the request of the medical society of the county in which the alleged misconduct or infraction of the act occurred.

(b) The commissioner shall remove from the list of physicians authorized to render medical care under this act the name of any physician who

(1) has been guilty of professional or other misconduct or incompetency in connection with medical services rendered under this act; or

(2) has exceeded the limits of his professional competence in rendering medical care under this act or has made materially false statements concerning his qualifications in his application for the recommendation of the medical society in the county in which his office is located, or of the board designated by it; or

(3) has failed to submit full and truthful reports required to be made by him to the commissioner; or

(4) has rendered medical services under this act for a fee less than that fixed by the commissioner as the minimum rate in his community; or

(5) has participated in the division, transference, assignment, rebating, splitting or refunding of a fee for medical care under this act; or

(6) has solicited, or has employed another to solicit, for himself or for another the professional treatment, examination or care of

an injured employee in connection with any claim under this chapter.

(c) Nothing in this section shall be construed as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, either before or after investigation by a medical society or board as herein provided, or to evoke the authorization of any physician or the license of any compensation medical bureau that he may determine to be guilty of such misconduct.

5. (a) The commissioner may, upon the recommendation of the medical society of each county or of a board designated by such county society, authorize and license compensation medical bureaus, maintained by qualified physicians wholly or principally for the diagnosis and treatment of industrial injuries or illnesses to render medical care under this act. Application for such authorization shall be made on forms to be furnished by the commissioner and shall disclose in full the nature of the personnel and equipment of such bureaus. No such authorization shall be made in the absence of recommendation from the appropriate society or board. Each such bureau which receives such authorization shall:

(1) Make reports on its personnel and equipment in such form and at such times as may be required by the commissioner; and

(2) be subject to inspection by the commissioner or the medical society of the county in which such bureau is located; and

(3) pay to the commissioner a license fee of twenty-five dollars per annum for each compensation bureau. The fees so collected shall be used for defraying the expense of licensing and inspecting such bureaus.

(b) The commissioner shall revoke the license of any compensation medical bureau upon finding that such bureau has been guilty of professional or other misconduct or of violation of the provisions of this act or that the personnel of such bureau is not properly qualified under this act or that the equipment of such bureau is inadequate for the proper rendering of medical care.

6. (a) Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by section 3 of this chapter to render medical care under this act, or to the agent or to the executor or administrator of the estate of such physician. Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services.

7. (a) Unless within thirty days after a bill has been rendered to the employer by the physician or hospital which has treated an injured employee, such employer shall have notified the commissioner and such physician or hospital in writing that such employer demands an impartial examination of the fairness of the amount claimed by such physician or hospital for his or its services, the right to such an impartial examination shall be deemed to be waived and the amount claimed by such

physician shall be deemed to be the fair value of the services rendered by him.

(b) If the parties fail to agree as to the value of medical services rendered under this act such value shall be decided by an arbitration committee consisting of two physicians designated by the president of the medical society of the county in which the claimant resides and two physicians also members of the Medical Society of the State of New York appointed by the employer or carrier. The majority decision of the arbitration committee shall be conclusive upon the parties as to the value of the services rendered, unless grossly excessive or inadequate or procured by fraud. In the event of equal division, the committee shall select a fifth physician, also a member of the Medical Society of the State of New York whose decision shall be conclusive.

(c) The parties to arbitration proceedings under this section shall each pay to the commissioner a sum equal to five percent of the award, or a minimum of two dollars. From sums so collected the commissioner shall pay to each member of the arbitration committee a per diem fee of ten dollars.

8. (a) Hospitals maintained wholly by public taxation may treat only emergency cases under this act, and may treat such emergency cases only so long as the emergency exists. This section shall not be applicable where there is not available a hospital other than a hospital maintained by taxation, nor shall it prevent any municipal, county or state hospital from rendering medical services to employees of such hospital.

9. Any person who shall make it a business to solicit employment for any person authorized by this act to render medical care to an injured employee in connection with any claim under this act, shall be guilty of a misdemeanor, except that the employer shall have the right, subject to regulations prescribed by the commissioner, to recommend to the injured employee the names of enrolled physicians who he believes to be competent to treat him.

10. (a) The primary determination of temporary partial, temporary total, permanent partial and permanent total disability and of the degree or percentage of partial disability and the primary determination of causal relationship of the disability to an injury or occupation, shall be the duty of the referee sitting in the case. When in doubt he may call an impartial medical expert specially qualified in the subject matter of the case as provided in paragraph c, subdivision 1, or he may refer the case for decision to the Medical Advisory and Appeal Board.

(b) In the end result after accident or accidents the following shall be used as a general guide for the determination of the degree of disability:

1. Function, or capacity to perform
2. Union, or state of repair of parts injured

3. Contour, or external appearance, including the presence or absence of facial or other disfigurements.

(c) A Medical Advisory and Appeal Board or Boards of three physicians shall be appointed for each compensation district of the State by the commissioner from a list of not less than nine physicians nominated jointly by the county medical societies of such district. When appeals in a given district are too numerous for a single board to adjudicate, two or more boards may be designated. When the county medical societies fail to make nominations for membership on the Medical Advisory and Appeal Board within sixty days after the commissioner requests such nominations, the commissioner shall appoint three qualified physicians to serve as the members of the board.

Referees may refer cases to the Medical Advisory and Appeal Board for the determination of disability or of causal relationship as provided in paragraph (a) of this subdivision. The Medical Advisory and Appeal Boards shall also hear all appeals from the decision of referees which involve (1) the determination of disability, (2) the determination of the degree or percentage of disability, (3) the determination of causal relationship of abnormal physical conditions arising out of employment, and (4) the determination of alleged prejudice with respect to immediate or ultimate result from failure to provide treatment for an employee by an employer or failure to accept treatment by the employee. The majority decision of the Board shall be conclusive.

The Medical Advisory and Appeal Boards shall not review cases in which a referee has referred the case to a specially qualified physician under paragraph (c) subdivision (1) and has made a decision in accordance with the findings and report of such physician.

(d) The commissioner shall pay to each member of the Medical Advisory and Appeal Board a per diem fee of twenty dollars and the expenses of transportation.

(e) The county medical societies shall be entitled to reimbursement by the commissioner for secretarial expenses incurred in (1) registration or enrollment of physicians under this act, (2) the investigation of charges filed against physicians under this act, (3) the inspection of compensation medical bureaus, (4) the activities of the arbitration committee, (5) the activities of the Medical Advisory and Appeal Boards and (6) other duties necessitated by this act.

11. (a) No physician, even if employed by the Department of Labor, can serve both as a witness and as advisor to the commissioner or referee at a hearing.

(b) Whenever his attendance at a hearing is required by a referee or by the Medical Advisory and Appeal Board, the physician of the injured employee shall be entitled to receive a fee of five dollars from the employer.

12. (a) An insurance carrier other than a self insured employer shall not participate in the treatment of injured workmen except that it may employ medical inspectors to examine compensation cases periodically while under treatment and report upon the adequacy of medical care and other matters relative to the medical conduct of the case.

(b) A self insured employer may maintain a compensation medical bureau at the place or places of employment if such bureau is required because of the nature of the industrial hazards or the frequency of injuries to

employees arising out of industry. Such bureau or bureaus shall be authorized and licensed pursuant to subdivision 5, and their use by an injured employee shall be optional in accordance with the provisions of paragraph (a) of subdivision 2.

Committee—Eugene H. Pool, M.D., Chairman; George Bachr, M.D., Secretary. Frederick W. Bancroft, M.D., David J. Kaliski, M.D., Adrian V. S. Lamber, M.D., Thomas A. McGoldrick, M.D., Charles A. McKendree, M.D., Frederick M. Miller, Sr., M. D., Harry R. Trick, M.D., Frederick S. Wetherell, M.D.

Committee on Public Health and Medical Education

Graduate Education

THE Committee announces a course on Dermatology in Onondaga County to start on January 11th.

Particular attention is called to a new course of lectures on Orthopedic Surgery. This course will consist of six lectures from a list of twelve practical phases. It should prove of special interest to those Counties where objections have been raised to the care of Orthopedic cases by the State Department of Health. Information can be obtained by writing to the Chairman, Dr. Thomas P. Farmer, 608 East Genesee St., Syracuse, N. Y.

New Member of the Committee

The vacancy caused by the sad and untimely death of Dr. Nellis B. Foster has been filled by appointment of Dr. Russell L. Cecil of New York City.

Malnutrition of Children Among Families Under Welfare Relief

The Committee views with deep concern the possibility that in the families who are on welfare relief the children may be seriously undernourished. Such a condition, pitiable in childhood, or even tragic, implies a potential handicap for the future adult. Therefore the Committee has given thorough consideration to the matter. Conferences have been held with Commissioner Parran and Dr. H. L. K. Shaw of Albany; and, finally, a recommendation was presented to the Executive Committee that the State Society sponsor surveys of actual conditions in a few special districts in order to determine to what extent such malnutrition may in fact exist.

While the work can be best conducted as a joint activity of a County Society and the State Department of Health, it is imperative that the Chairmen of local Public Health Committees, who may be involved, shall direct the surveys. Further advice on this subject will be issued.

Public Health Plus Medical Education

This Committee, as its title indicates, is charged with a double duty.

Most happily has this twofold purpose been realized in the following presentation from

Monroe County, which was prepared at the instance of this Committee.

It is clearly to be seen, therein, that aggressive and sustained action by an enlightened County Society, in the effort to better public health, necessarily brings in graduate medical education.

This Committee commends most highly the Monroe County work so well described by Dr. Whipple.

An Effort in Graduate Education by the Public Health and Graduate Education Committees of the Medical Society of the County of Monroe

FOUR years ago the Public Health Committee of the Medical Society of the County of Monroe was reorganized into an active committee with a chairman and twelve members. Three were members-at-large and nine became chairmen of subcommittees.

The motive prompting the activities of this committee was the belief that organized medicine should assume leadership in local health activities and that this Society could coordinate these activities in the interest of efficiency. A full report of results will be made at a later date; but it is believed that results already obtained prove the energy well expended from the standpoint of both the Society and the public.

After three years of active interest on the part of nine subcommittees it was apparent that the public was aware of an attempt to give them truth in medicine through broadcasting and lectures. A sound health-mindedness has resulted. The social agencies interested in health work have increasingly sought advice and counsel of the Society. The official health agency, the Health Bureau, through its health officer, has felt the benefit of advice. Close co-operation has been advantageous and very mutual. An increased interest in the work of the local tuberculosis sanitarium and a more understanding relationship between the staff and physicians of the committee now exist. Through the efforts of the committees it is believed that the Society membership has learned to think and act as a society rather than as individuals. All have been brought in closer contact with national and local tubercu-

losis, heart, cancer and social hygiene groups, better appreciating the magnitude of the efforts in disease prevention.

Noting well these results, there was nevertheless another observation which concerned the Society. Without proof from any definite figures it was generally felt that efforts directed toward having the public seek its physicians for advice, caused an increased number of consultations. Then arose these specific questions: If, after advice to the public over the radio or otherwise to seek its family physicians, did those physicians understand and correctly use tuberculin and the x-ray in diagnosis and in follow-up examinations of an arrested case? Regarding the diagnosis and treatment of heart disease, did the physician appreciate rheumatic and degenerative heart disease as he should? Did every rapid heart mean to him the administration of digitalis? If, after arousing interest in venereal disease, could the family physician adequately treat such cases. These and many other questions arose which resulted in an effort to give the physicians of the community some constant graduate work, lest it be found that the public demand more of the physician than he could or would give them.

The Public Health Committee called into council the Graduate Education Committee and later the local Academy of Medicine became a participating group. The program has proceeded under the guidance of the Graduate Education Committee—the subcommittees of the Public Health Committee originating and executing their own program. One week's graduate education has been supplied by the Medical Society of the State of New York through its Public Health and Medical Education Committee. This has been well attended and the material presented of exceptional value. This educational opportunity is acknowledged to be a big feature of the year-round program. Rochester University through its medical school has provided an interesting and valuable series of graduate lectures which greatly helps. Local hospitals have provided clinic days open to the profession at large conducted by members of the staff, continuing throughout the day, including in one hospital a lunch for which twenty-five cents is charged. These efforts of the medical school and hospitals are independent of the County Society's activities but are mentioned as necessary adjuncts to any Society's program and should be included when possible in planning such a program.

The subcommittee on tuberculosis has already started its program by the presentation of a symposium on tuberculosis before the Society membership. The subjects presented were:

- (1) *Is There Still a Tuberculosis Problem?*
- (2) *What Are the Essentials in an Ideal Community Program?*
- (3) *Why Reporting of Positive Cases Is Necessary?*

- (4) *What Is Case Finding?*
- (5) *What Is New in Treatment?*
- (6) *After Recovery—What?*

General discussion followed, led by the Director of the Division of Tuberculosis of the State Department of Health. At the close of the meeting each physician present was given a printed bound copy of the papers presented in the symposium and later a copy was sent to every member of the County Society not present. This was done as a committee effort and no names appeared in the printed copy of papers. There was presented in the Academy at the time of the meeting an exhibit of x-ray films from the local tuberculosis sanitarium showing all types of tuberculosis, diseases to be differentiated from tuberculosis and the effects of surgical measures used in treatment.

At frequent intervals from now on demonstrations in methods of examination and interpretation of physical signs, in the use of tuberculin, and in the value and interpretation of x-ray films, will be given in the local tuberculosis sanitarium and various hospitals. Monthly abstracts supplied by the National Tuberculosis Association are mailed to each member. Similar Society programs and exhibits, reviews of current literature, are to be presented by each of the subcommittees, modified as seems advisable to best meet the subject.

The problem of reaching those who do not wish to learn and those who do not attend medical meetings still is unsolved, but we believe that but few men in this county will escape, at least the opportunity to know that their County Society expects them to adequately meet the demands of the public.

An effort of this character entails work. As an example—the tuberculosis subcommittee made a complete survey of the local tuberculosis situation. This alone was no small task. Weekly meetings were held for approximately three months. Each article presented was reviewed by the entire committee. A meeting was held with the local Roentgen Ray Society to discuss the economic aspect of x-ray diagnosis, resulting in their cooperation. Each subcommittee presenting its subject must necessarily devote time and effort. The heart committee has, for instance, made surveys in some of the public schools, the results of which are used as valuable material in exhibits and papers.

Thus, a program of graduate education is being attempted, partly in the interest of the membership and partly in self defense. We believe a similar program can be carried out in larger centers and modified for use in smaller societies whose membership extends over a greater area.

E. G. Whipple, M.D., Chairman, Public Health Committee of the Medical Society of the County of Monroe.

12. (a) An insurance carrier other than a self insured employer shall not participate in the treatment of injured workmen except that it may employ medical inspectors to examine compensation cases periodically while under treatment and report upon the adequacy of medical care and other matters relative to the medical conduct of the case.

(b) A self insured employer may maintain a compensation medical bureau at the place or places of employment if such bureau is required because of the nature of the industrial hazards or the frequency of injuries to

employees arising out of industry. Such bureau or bureaus shall be authorized and licensed pursuant to subdivision 5, and their use by an injured employee shall be optional in accordance with the provisions of paragraph (a) of subdivision 2.

Committee—Eugene H. Pool, M.D., Chairman; George Bachr, M.D., Secretary.

Frederick W. Bancroft, M.D., David J. Kahski, M.D., Adrian V. S. Lamber, M.D., Thomas A. McGoldrick, M.D., Charles A. McKendree, M.D., Frederick M. Miller, Sr., M. D., Harry R. Trick, M.D., Frederick S. Wetherell, M.D.

Committee on Public Health and Medical Education

Graduate Education

THE Committee announces a course on Dermatology in Onondaga County to start on January 11th.

Particular attention is called to a new course of lectures on Orthopedic Surgery. This course will consist of six lectures from a list of twelve practical phases. It should prove of special interest to those Counties where objections have been raised to the care of Orthopedic cases by the State Department of Health. Information can be obtained by writing to the Chairman, Dr. Thomas P. Farmer, 608 East Genesee St., Syracuse, N. Y.

New Member of the Committee

The vacancy caused by the sad and untimely death of Dr. Nellis B. Foster has been filled by appointment of Dr. Russell L. Cecil of New York City.

Malnutrition of Children Among Families Under Welfare Relief

The Committee views with deep concern the possibility that in the families who are on welfare relief the children may be seriously undernourished. Such a condition, pitiable in childhood, or even tragic, implies a potential handicap for the future adult. Therefore the Committee has given thorough consideration to the matter. Conferences have been held with Commissioner Parran and Dr. H. L. K. Shaw of Albany; and, finally, a recommendation was presented to the Executive Committee that the State Society sponsor surveys of actual conditions in a few special districts in order to determine to what extent such malnutrition may in fact exist.

While the work can be best
joint activity of a County
State Department of Health,
that the Chairmen of local
Committees, who may
the surveys. Further
will be issued.

Public Health

This C...
charged with a d...
Most happily
realized in the f

Monroe County, which was prepared at the instance of this Committee.

It is clearly to be seen, therein, that aggressive and sustained action by an enlightened County Society, in the effort to better public health, necessarily brings in graduate medical education.

This Committee commends most highly the Monroe County work so well described by Dr. Whipple.

An Effort in Graduate Education by the Public Health and Graduate Education Committees of the Medical Society of the County of Monroe

FOUR years ago the Public Health Committee of the Medical Society of the County of Monroe was reorganized into an active committee with a chairman and twelve members. Three were members-at-large and nine became chairmen of subcommittees.

The motive prompting the activities of this committee was the belief that organized medicine should assume leadership in local health activities and that this Society could coordinate these activities in the interest of efficiency. A full report of results will be made at a later date; but it is believed that results already obtained prove the energy well expended from the standpoint of both the Society and the public.

After three years of active interest on the part of nine subcommittees it was apparent that the public was aware of an attempt to give them truth in medicine through broadcasting and lectures. A sound health-mindedness has resulted. The social agencies interested in health work have increasingly sought advice and counsel of the Society. The official health agency, the Health Bureau, through its health felt the benefit of advice. Close contact has been advantageous and very increased interest in the work of the tuberculosis sanitarium and a more relationship between the staff of the committee now exist. Reports of the committees it is a society membership has acted as a society rather have been brought in and local tubercu-

losis, heart, cancer and social hygiene groups, better appreciating the magnitude of the efforts in disease prevention.

Noting well these results, there was nevertheless another observation which concerned the Society. Without proof from any definite figures it was generally felt that efforts directed toward having the public seek its physicians for advice, caused an increased number of consultations. Then arose these specific questions: If, after advice to the public over the radio or otherwise to seek its family physicians, did those physicians understand and correctly use tuberculin and the x-ray in diagnosis and in follow up examinations of an arrested case? Regarding the diagnosis and treatment of heart disease, did the physician appreciate rheumatic and degenerative heart disease as he should? Did every rapid heart mean to him the administration of digitalis? If, after arousing interest in venereal disease, could the family physician adequately treat such cases? These and many other questions arose which resulted in an effort to give the physicians of the community some constant graduate work, lest it be found that the public demand more of the physician than he could or would give them.

The Public Health Committee called into council the Graduate Education Committee and later the local Academy of Medicine became a participating group. The program has proceeded under the guidance of the Graduate Education Committee—the subcommittees of the Public Health Committee originating and executing their own program. One week's graduate education has been supplied by the Medical Society of the State of New York through its Public Health and Medical Education Committee. This has been well attended and the material presented of exceptional value. This educational opportunity is acknowledged to be a big feature of the year-round program. Rochester University through its medical school has provided an interesting and valuable series of graduate lectures which greatly helps. Local hospitals have provided clinic days open to the profession at large conducted by members of the staff, continuing throughout the day, including in one hospital a lunch for which twenty-five cents is charged. These efforts of the medical school and hospitals are independent of the County Society's activities but are mentioned as necessary adjuncts to any Society's program and should be included when possible in planning such a program.

The subcommittee on tuberculosis has already started its program by the presentation of a symposium on tuberculosis before the Society membership. The subjects presented were

- (1) *Is There Still a Tuberculosis Problem?*
- (2) *What Are the Essentials in an Ideal Community Program?*
- (3) *Why Reporting of Positive Cases Is Necessary?*

(4) *What Is Case Finding?*

(5) *What Is New in Treatment?*

(6) *After Recovery—What?*

General discussion followed, led by the Director of the Division of Tuberculosis of the State Department of Health. At the close of the meeting each physician present was given a printed bound copy of the papers presented in the symposium and later a copy was sent to every member of the County Society not present. This was done as a committee effort and no names appeared in the printed copy of papers. There was presented in the Academy at the time of the meeting an exhibit of x ray films from the local tuberculosis sanitarium showing all types of tuberculosis, diseases to be differentiated from tuberculosis and the effects of surgical measures used in treatment.

At frequent intervals from now on demonstrations in methods of examination and interpretation of physical signs, in the use of tuberculin, and in the value and interpretation of x ray films, will be given in the local tuberculosis sanitarium and various hospitals. Monthly abstracts supplied by the National Tuberculosis Association are mailed to each member. Similar Society programs and exhibits, reviews of current literature, are to be presented by each of the subcommittees, modified as seems advisable to best meet the subject.

The problem of reaching those who do not wish to learn and those who do not attend medical meetings still is unsolved, but we believe that but few men in this county will escape, at least the opportunity to know that their County Society expects them to adequately meet the demands of the public.

An effort of this character entails work. As an example—the tuberculosis subcommittee made a complete survey of the local tuberculosis situation. This alone was no small task. Weekly meetings were held for approximately three months. Each article presented was reviewed by the entire committee. A meeting was held with the local Roentgen Ray Society to discuss the economic aspect of x ray diagnosis, resulting in their cooperation. Each subcommittee presenting its subject must necessarily devote time and effort. The heart committee has, for instance, made surveys in some of the public schools, the results of which are used as valuable material in exhibits and papers.

Thus, a program of graduate education is being attempted, partly in the interest of the membership and partly in self defense. We believe a similar program can be carried out in larger centers and modified for use in smaller societies whose membership extends over a greater area.

County News

[News items of general state wide interest will be welcomed from all members who are asked to submit them through their County Society reporters.]

Albany

Close Accord between City Administration and County Society: At the Annual Dinner Meeting of the Society on December 12th, 1933, Mayor John Boyd Thacher declared himself as in complete sympathy with the Albany Society in opposition to the modern socialistic tendencies now cropping out in medical circles. The Mayor was particularly emphatic in expressing his desire to bring back to the family physician such work as Vaccinations, administration of Toxoid and Toxin-Antitoxin, and the proposed city wide examination of school children for tuberculosis.

Suffolk

An Innovation Suggested—In his recent Presidential address, appearing in the News Letter for December, 1933, Dr. Louis F. Garben suggested that the Society advocate a change in the Medical Practice Act to make membership in a County Medical Society a "requisite for obtaining a license to practice medicine." He had gained the notion from study of the customs of Denmark where

"County Societies can determine whether a given doctor is or is not allowed to practice," and where expulsion from the Medical Society is "tantamount to revocation" of license to practice.

Meeting of Suffolk County Public Health Nurses' Association—On November 20th, 1933, Dr. B. P. McLean, Deputy Commissioner, addressed the meeting on "Placing Responsibility for Positive Health in Preventive Medicine." He stressed the necessity for co-operation between an enlightened Public and the Medical Profession in order to secure further progress in prevention.

Westchester

Value of Medical Charity in Hospitals of the County—A careful survey recently concluded by the local Economics Committee has yielded definite figures for the value of free medical attendance rendered by private physicians in the wards of hospitals in the County. Thirteen out of a total of fifteen hospitals supplied accurate figures to which were added minute estimates for the remaining two.

In the year 1932 thus:—

17,117 persons received free care in Wards,

56,171 persons received free care in Dispensaries.

A rough but conservative estimate of value of a full day's medical attendance was set at \$3.00, of a major operation at \$100.00, of a minor operation at \$25.00, of an obstetrical delivery at \$50.00, of a dispensary treatment or consultation at \$2.00.

"On this basis we find that the medical staffs of Westchester County Hospitals have contributed in one year service in medical attendance to ward bed patients equivalent to \$947,325; in major operations the equivalent of \$325,600; in minor operations, \$127,050; in obstetrical deliveries \$89,250; in dispensary consultations and treatments \$368,648. Adding these figures together, we note that the attending physicians and surgeons of the fifteen general hospitals of the County have contributed to the poor in these institutions in a period of 12 months, medical and surgical attendance conservatively worth \$1,857,873."

RADIOTHERAPY IN DISSEMINATED SPINAL ARACHNOIDITIS

By HERMAN SELINSKY, M.D., and WILLIAM HARRIS, M.D.

From the Neurological and Radiotherapy Departments of Mount Sinai Hospital, New York City

Read at the Annual Meeting of the Medical Society of the State of New York, April 5, 1933, New York, N. Y.

VARIOUS neurological conditions which are accompanied by pain when treated by the roentgen ray, yield favorably to this form of therapy. This observation is perhaps best illustrated in local or metastatic malignant disease involving the spinal column and pelvis where pressure upon the spinal cord and its roots produces pain. The distressing symptoms associated with intramedullary disease of the spinal cord (e.g., syringomyelia) yield favorably to radiation therapy. Radiculitis secondary to spondylitis also responds well to radiotherapy in a certain number of cases.¹ Although the application of radiotherapy in infectious processes is mainly empirical—for there is no sound evidence to prove that it possesses bactericidal powers—we do know that the productive tissue proliferation in inflammatory processes is extremely radiosensitive.² With these facts in mind, radiation therapy suggested itself to us as an agent which might be beneficially utilized in the treatment of disseminated spinal arachnoiditis.

Clinical Features.—Spinal arachnoiditis was first described as a clinical entity by Spiller³ in 1903. In this communication, attention was drawn to the history of pain in the extremities, with objective evidence of spinal-cord involvement. Pathologic findings consisting of thickened, inflamed arachnoid adhesions were noted. Later, Stookey⁴ in a review of this clinical problem, summarized his extensive experience in the surgical treatment of this disease. In the cases reported by him emphasis was placed upon the picture of spinal-cord compression simulating tumor. While some of the cases showed an excellent response to surgical intervention, Stookey implied that in the more extensive processes, surgery was

limited in its scope as the field of exposure is of necessity restricted.

Etiology.—The etiology of this condition is at present obscure. While most of the cases do not show arthritis roentgenographically, the presence of osteoarthritis of the spine in some instances may lead one to believe that there may be a relationship between the two conditions. In a number of cases the history of an antecedent pneumonic or pleuritic infection has been obtained. This suggested the possible extension of the infectious process to the arachnoid and the spinal roots. Recurrent attacks of tonsillitis or the presence of dental disease may also play a rôle as a possible focus of infection, such factors having been elicited in two of our cases. The older views frequently mention syphilis as an important source of infection in spinal arachnoiditis. However, the serology in all of our cases has been negative.

Symptomatology.—There is a history of pain in one or more extremities or over the trunk. The pain is of peculiar type resembling that due to posterior spinal-root irritation; it may continue over a period of months before a physician is consulted and involves at various times different extremities, with remissions and exacerbations.

Objective findings are noted which point to a polyradicular involvement sometimes associated with evidence of spinal-cord impairment. These findings are sensory disturbances which are radicular in character and an alteration in the deep reflexes.

Diagnosis.—The diagnosis of this condition is based upon the history, pain in the extremities or trunk, the objective neurological pattern of a polyradicular disorder, and the confirmatory evidence of partial or complete block in the spinal subarachnoid space. The latter is discovered first, by the Queckenstedt test with the characteristic delay in the fall

and rise of the fluid in the manometer; second, by contrast myelography utilizing iodized oil which is a graphic means of indicating the disseminated character of the disease process (Fig. 1). The clinical features are perhaps best shown in the illustrations of case histories.

Case Reports.—The present series consists of 5 cases. For purposes of expediency the records of only 2 cases, typical of the clinical picture and the response to x-ray therapy, are presented:

Fig. 1.—(a) Normal descent of lipiodol. (b) Scattered arrest typical of arachnoiditis.

Fig. 3a

CASE 1.—M. C., nurse, 27 years of age, was first seen in September, 1928. Her complaint consisted of shooting pain progressively involving all of the extremities and the face for one and a half years. Findings on admission consisted of: zones of hyperalgesia, radicular in pattern (as charted) and difference in the deep reflexes (Fig. 2). The Queckenstedt test showed a partial block. Lipiodology performed by cisternal injection revealed an arrest of oil droplets as seen in radiographs (Fig. 3).

The treatment first given to the patient consisted of analgesics and foreign-protein therapy. Very little improvement was noted either by the patient or by the examining physician. Following deep x-ray therapy she obtained striking relief from the pain, and when, in 1931, the pain recurred, repetition of the x-ray therapy resulted in complete disappearance of the pain.

Present Status:—patient is working actively, and has no discomfort.

On examination, there are noted areas of hyperalgesia at C8-D1 on the left side, and at L5-S2 bilaterally (absence of any subjective symptoms).

Fig. 2—Case 1, Marian C. (1) Right KJ and AJ greater than left. (2) Weakness of left upper and lower extremities. (3) No pyramidal tract signs.—Queckenstedt: partial block.

Fig. 3b

CASE 2.—M. C., male, aged 59. This patient gave a history of gonorrheal infections on two occasions in his youth. He was first admitted to the service of Dr. I. Strauss in 1927, with a history of pain in the legs of six years' duration. This was relieved after the removal of diseased teeth. About the time of admission he suffered a return of pain in the left lower extremity. Three epidural injections were given without relief of symptoms. The signs on admission: Hypalgesia

L5 S1, diminished I A J, bilateral Lasegue sign (Fig 4)

The first Quackenstedt test showed a rather dubious delayed rise and fall. A subsequent test failed to confirm the presence of partial block. Lipiodolography showed an arrest of the oil as seen in the radiograph (Fig 5). Immediately following this procedure the patient complained of exacerbation of pain in both lower extremities. Laminectomy was performed and a bony prominence at L2 was found which was interpreted as an osteoma; however, there was no specimen re-

Fig 4—Case 2, Morris C (1) Tenderness over lumbar spine (2) Diminished abdominal reflexes (3) Lasegue sign on left (4) Diminished left A J—Quackenstedt 1927 partial block (?) 1930 negative

moved for histologic study. Following the operation, the patient felt definite symptomatic improvement. Three years later, in 1930, a return of pain in the lumbar region compelled the patient to enter the hospital again for treatment. The Quackenstedt test was negative for block, the spinal fluid was clear and contained two cells per cubic centimeter. The patient was treated with salicylates, baking, and diathermy, these measures affording him moderate relief. In 1931 he came to the out-patient department complaining of burning pain in the back and a burning sensation in both feet, cramp like in character. It was suspected that the patient might have arachnoiditis and he was referred for radiography, which demonstrated a scattering of lipiodol confirming the clinical impression of arachnoiditis. He was then sent for deep x-ray therapy and complete cessation of pain was obtained. He returned in March, 1932, because of a recurrence of the cramp like burning pain in the left foot. Following a second course of treatment the patient suffered only one attack of this pain in the subsequent six months. The objective sensory findings at the present time do not show any deviation from the normal. There is however a persistent diminished left Achilles jerk.

Treatment—The results obtained with roentgenotherapy have been gratifying and showed a distinct advantage over all other forms of treatment which were previously employed. Since there is a definite tendency for these painful attacks to recur at varying intervals, the treatment may be repeated as

the occasion warrants up to the point of skin tolerance to radiation. The technique employed may be summarized as follows:

High voltage roentgen radiation was directed to the spine by cross-firing.

The point of attack was indicated by the level or levels of sensory disturbances. Depending upon the response to the therapy, one or more series were given. Series of treatments were repeated at six weeks intervals if the indications so warranted.

Figure 5

Fractional treatments were given at each sitting consisting of 100 to 250 roentgen units until a total of 900 roentgens had been administered. The factors used were 180 kilovolts, a filter of 0.5 mm copper and 1 mm aluminum, 1 m, 10 to 50 cm focal skin distance.

Summary

Disseminated spinal arachnoiditis is a condition characterized by signs and symptoms of a polyradicular disturbance, sometimes associated with mild spinal cord involvement. The etiology is as yet obscure. Evidence of block in the subarachnoid space is shown by the Quackenstedt test, and by contrast myelography showing the disseminated character of the disease process. There is a tendency for a recurrence. Roentgen therapy has proved to be a valuable therapeutic measure in this condition.

70 EAST 77TH STREET

CRANIAL NEURITIS

By SAMUEL BROCK, M.D., and S. BERNARD WORTIS, M.D.
New York City

Read at the Annual Meeting of the Medical Society of the State of New York, April 5, 1933, New York, N. Y.

In the past two years the writers have observed 4 instances of cranial neuritis in the course of herpes zoster, dental and general infections. While different observers have reported somewhat similar cases, this group is an unusual one because of the clinical signs and course, the association of uveitis in 2 of the cases and the problem arising in connection with the probable virus etiology and its mode of dissemination. In his Morison lectures on peripheral neuritis, James Collier¹ gives an excellent analysis of the rich clinical material observed by him in his long career. He lays particular stress on the types of neuritis of probable virus origin, the ascent of the virus by way of the axones, the widespread involvement of the nervous tissues, and the "extraneuronic delivery of the virus" from the nerve terminals, *viz.*, to the salivary glands in rabies and to the dermatomic skin areas in herpes.

CASE 1.—M. R., a merchant, 39 years of age, was admitted to Beth Israel Hospital on November 30, 1931.

Ten days before admission, the patient was awakened from sleep by acute "sticking" sensations in the back of the left shoulder. Shortly afterward he complained of occasional chills and warm "flashes" and the pain returned and radiated down the left arm and forearm; it was severe enough to disturb his sleep. On the day before admission, while walking about, he felt a sudden severe pain over the upper part of the sternum associated with a feeling of fulness, substernal tightness, and a choking sensation. He experienced some difficulty in catching his breath. Because of the symptoms he was admitted to the hospital as a case of possible coronary thrombosis.

After he had been in the hospital for a few hours, a right peripheral facial paralysis appeared, to which was added a left peripheral facial paralysis about twelve hours later.

The past history was irrelevant. He has stuttered since early childhood.

On the day after admission the neurological examination disclosed the following abnormalities: bilateral facial paralysis of the peripheral type with inability to blow out the cheeks, show the teeth, wrinkle the forehead or close the eyes completely. Innervation of the vocal cords was normal. There was absence of knee and ankle jerks and mild sensory changes of radicular type, especially on the left. Weakness of the hamstring and quadriceps femoris muscles developed in the next two days. The muscles of the back and of the lower abdomen then became affected in consequence of which he was unable to sit up or expel enemata. In the upper

extremities weakness of the triceps was very marked. Later, the abdominal and cremasteric reflexes disappeared. There was diminution of all forms of sensation in the lower extremities with an indefinite level at about D-12. Pain was complained of in the lower extremities; the calves were tender to pressure. No pathological reflexes were noted. The following week, weakness appeared in the muscles of the shoulder girdle, in the extensors of the elbows and wrists, and in the muscles about the hip joint. Retention of urine occurred.

Three weeks after admission, the patient for the first time presented atrophy and furring of the right side of the tongue and upon protrusion, it deviated to the right.

The pulse rate throughout the illness varied from 80 to 96; the systolic blood pressure measured 136 to 160 mm. Hg; the diastolic 92 to 106. The temperature was normal.

There was no evidence of cardiac disease.

Laboratory Findings.—The red and white blood counts and blood sugar estimations were normal. Repeated urine examinations showed varying numbers of granular and hyaline casts. The blood and spinal fluid Wassermann reactions were negative; the spinal fluid was normal.

X-ray examination of the heart and lungs and electrocardiogram revealed no abnormalities.

Electrical tests of involved muscles showed absence of faradic reaction; the galvanic reaction was present with a greater cathodal than anodal response.

The patient received five intravenous injections of typhoid vaccine beginning with 5 million and going up to 100 million. The average elevation of temperature was between $\frac{1}{2}$ and 1 degree. These injections were followed by eight radiotherapy treatments with an average rise of temperature to 102.2° F. Massage and galvanic stimulation of the muscles were also given.

After one month gradual improvement occurred. The facial paralysis completely disappeared. The unilateral hypoglossal weakness improved markedly. Power in the musculature of the extremities returned. The atonic abdominal muscles became stronger. Normal bladder function returned. The sensory changes and the spontaneous pains in the extremities receded. He was discharged on February 11, 1932. At that time he was able to walk about fairly well and his general condition was good.

He was examined again on January 25, 1933. Motor, sensory, and reflex functions were quite normal. However, he complained of occasional numbness in the fingers of both hands, more so on the left, and in all the toes. Occasionally, a choking substernal sensation bothered him. A slight pain in the occipital region and left temple appeared at times.

Comment.—There are a number of noteworthy features in this case. The onset with symptoms so suggestive of coronary vessel dis-

ease is unusual. Indeed, one is led to suspect that the affection involved the cardiac vegetative fibers early in its course, implicating the very nerve elements (pre- or postganglionic) that transmit the anginal type of pain, often related to coronary disease. To pursue this speculation further would lead us too far afield.

The quick spread and severity of the polyneurotic signs, the marked involvement of the proximal muscles, and the comparatively rapid improvement are also of interest. This speedy recovery is in accord with the assumed peripheral localization of the pathology. One would suspect that the connective rather than the parenchymal tissues of the nerves are mainly affected, producing the type of "interstitial neuritis" described by Collier. Nothing is known concerning the etiological agent.

Similar cases have been reported by Osler¹ under the title "acute febrile polyneuritis." Later, Holmes², Bradford, Bashford and Wilson³, Viets⁴, and Taylor⁵ added other instances. Bradford notes that the "remarkably constant bilateral affection of the face is a very striking feature of the disease, as is also the involvement of the muscles of the trunk. Further, the presence of generalized weakness rather than of actual paralysis of individual muscles or groups of muscles is very characteristic. Again, the progressive nature of the palsy and its occasional ascending character together with the curious manner in which the proximal segments of the limbs with their large muscles are mainly involved, are all striking features in this disease and are not, at any rate, familiar observations in other affections of the nervous system."

CASE 2.—J. F., chauffeur, aged 25, was admitted to Bellevue Hospital, September 24, 1930. He complained of severe pain and a vesicular eruption along the third, fourth, and fifth left intercostal spaces. Three weeks before admission (seventeen days after onset) he noticed difficulty in smiling and talking.

The previous history was irrelevant.

Neurological examination revealed the following positive findings: bilateral facial paralysis with involvement of taste. There was no motor weakness of the extremities but the left knee jerk and both ankle jerks were absent. Sensation was normal.

Laboratory Findings.—The blood chemistry was normal. The blood count showed 11,000 white blood cells, 64 per cent polynuclears, 28 per cent lymphocytes, 4 per cent transitional cells, and 4 per cent basophiles; the red blood cells numbered 4,592,000 with 80 per cent hemoglobin. The blood Wassermann reaction was negative. The urine was normal. The spinal fluid Wassermann reaction was negative; the colloidal gold—001 2232 100. The record of the cell count and globulin estimation was lost.

X-rays of the skull and sinuses were normal.

Seventeen days after onset of the facial paralysis, the electrical reactions in the left facial muscles disclosed no response to faradism; galvanism gave a slow reaction (*i.e.*, R.D.). On the right, there was slight response to faradism and a rapid reaction to galvanism.

The patient improved while in the hospital and was discharged on October 14, 1930, six weeks after the onset. Unfortunately, the patient did not return for reexamination.

Comment.—Facial paralysis, whether uni- or bilateral, is a rare complication of herpes zoster the virus nature of which is fairly well established. Moreover, it seems evident that the herpes virus affects the facial nerve by way of the blood stream. It is worth pointing out that mild peripheral nerve involvement also occurred in this patient as shown by the loss of the deep reflexes in the lower extremities. Booth⁶ has described herpes zoster associated with facial paralysis. A particularly apt quotation from Collier's Morison lectures may be made at this point: "Bell's palsy, regarded as a local fibrositis with compression of the facial nerve in its canal by swelling of its sheath, and with external signs of pain and swelling in the region of the styloid process, was proved years ago by Ramsay Hunt in some of the cases to be a herpes zoster proper, by his demonstration of the herpetic vesicle in the external auditory meatus and his demonstration of the lesion in one case in the geniculate ganglion. Further, there were other cases in which there was no meatal vesicle, but zoster was coincident in some other region of the body, proving that facial paralysis without local herpetic signs could result from zoster infection. *A priori*, a great many of the cases of Bell's paralysis from exposure to cold might well be of herpetic origin."

CASE 3.—G. L., court interpreter, aged 50, entered The Neurological Institute of New York, September 30, 1931, complaining of redness of the right eye beginning four weeks before admission. One week later he noticed redness of the left eye; the following day photophobia was so troublesome that he was obliged to wear dark glasses. Fourteen days after the onset he experienced severe pain in the thoracolumbar region. Seven days later, right facial paralysis appeared followed by left facial involvement; as a result, he could not whistle or smile, and closing the eyes became difficult. He then saw double and was annoyed by tinnitus in the left ear. There was no vertigo. There was no fever at any time during his illness.

The past history was irrelevant.

Neurological examination revealed the following: bilateral peripheral facial paralysis and a diplopia on divergence which soon disappeared. There was no evidence of any other peripheral nerve involvement.

The ophthalmologist reported marked bilateral ciliary injection with inflammation of the entire uveal tract (bilateral uveitis).

Laboratory Findings.—The blood examination revealed: white blood cells, 8,000, 70 per cent polynuclears, 27 per cent lymphocytes, 3 per cent eosinophiles. The hemoglobin was 87 per cent. The red blood cells numbered 4,880,000; the color index was 0.9. The blood chemistry and Wassermann were normal. The urine was normal. Manometric estimation of the spinal fluid showed normal pressure and no block. The fluid was clear, contained 81 cells (94 per cent lymphocytes, 3 per cent polynuclears, 3 per cent large mononuclears); the globulin was 2 plus, the protein increased (92 mg.); the Wassermann reaction was negative, and the colloidal gold 111 1221 000 (October 2, 1931). Again on October 12, 1931, the spinal fluid showed 73 cells, an increase of protein (72 mg.), negative Wassermann reaction and increased globulin.

X-rays of the skull were normal; there was slight calcification in the region of the choroid plexus. Chest roentgenograms showed evidence of old bronchitis and an old healed right pleuritic lesion.

Because of the coincidence of uveitis and the facial paralysis, antiluetic treatment (mercury inunction and potassium iodide) was instituted for a period of about two weeks and was discontinued when sero-logical studies were found negative.

The patient began to improve and was discharged on October 21, 1931. His subsequent improvement was rapid and complete.

Comment.—The association of bilateral iridocyclitis with cycloplegia, bilateral parotitis, bilateral facial paralysis and mild generalized polyneuritis, with or without an erythematous rash, was described by Feiling and Viner³ in 1922. We believe that our case is similar, although there was no evidence of parotitis or limb polyneuritis. It would seem that we are dealing with a blood-borne virus infection first evidenced by conjunctival and uveal inflammation. Involvement of the parotid glands and perhaps other peripheral nerves bespeaks widespread diffusion.

CASE 4.—E. P., a sea captain, 34 years of age, was first seen in November 1932 at the U. S. Marine Hospital, New York, N. Y.

About September 10, 1932, an "infected tooth" in the right upper jaw began to hurt him. The pain spread to the right side of the face, which became swollen. After four weeks two teeth in the right upper jaw were extracted. Though the face remained swollen, the pain was relieved. However, in about a week the pain in the right face returned and the adjacent forehead and scalp on that side became sensitive. In addition, the right eye was "sore and reddened."

The past history was irrelevant.

The neurological examination, two months after onset (November 11, 1932), revealed the following positive findings: a definite right ptosis with a questionable proptosis of that eye. The right pupil was smaller than the left; both pupils were irregular. There was a questionable weakness of the left external rectus muscle. The disks were normal. The corneal reflexes were equally active. No sensory, vasomotor, or secretory abnormalities could be demonstrated on the skin of the face.

Three months after onset, December 19, 1932, Dr. C. R. Franklin made the following ophthalmological note: The right eye shows moderate ptosis and moderate injection of bulbar and tarsal conjunctiva; the iris is slightly atrophic. The pupil reacts consensually and directly and is slightly irregular. The lens is clear. The vitreous shows some very fine floating vitreous opacities (uveitis). There is a definite haziness of the nasal margin of the right nerve head. There is a paresis of the left external rectus as shown by gross observation and diplopia test, together with a definite anisocoria (the right pupil being constantly smaller than the left pupil).

Four days later both optic disks appeared normal and were clearly outlined. The smaller right pupil, the right ptosis and the slight left external rectus weakness persisted. His right facial pain was diminished. One week later, he went back to work.

Laboratory Findings.—The blood Wassermann reaction was negative. The urine was normal. The spinal fluid examination (December 22, 1932) disclosed 2 cells; normal globulin; colloidal gold curve—112 1000 000; and a negative Wassermann reaction.

X-ray examination of the skull showed no evidence of fracture or increased intracranial pressure.

He received considerable dental treatment from November 11th to December 29th, 1932, diathermia was given daily to the region of the right gasserian ganglion.

Comment.—The history and findings suggest a toxic or infectious condition arising at the site of the dental infection and ascending most likely by way of the axones of maxillary trigeminal fibers rather than by the perineural lymphatics. Indeed, the very existence of the latter is strongly doubted by some investigators. The trigeminal branches or ganglion and the paratrigeminal sympathetic fibers were partially involved in the neighborhood of the right cavernous sinus; to the former implication may be ascribed the pain in the face and forehead, to the latter the ptosis and miotic pupil (Horner syndrome). The slight right proptosis, the involvement of right optic nerve and the right eye (uveitis) add further weight to this conception of the spread and final localization of the noxious agent.

Such cases are seldom recorded and their incidence is difficult to estimate. In 1924, Raeder² reported 5 cases of paratrigeminal paralysis of the oculo pupillary sympathetic. In 2 cases head trauma (fractures of middle fossa) was responsible; in a third case an endothelioma was the cause, and in the remaining 2, the etiology was undetermined. Raeder placed the pathology in the region of the gasserian ganglion and adjacent cavernous sinus. A toxic or infectious etiology was not responsible in any of his cases. Bing¹⁰ illustrated the case of a woman with left trigeminal herpes zoster associated with left-sided miosis, enophthalmos and ptosis (Horner syn-

drome). Probably dentists see such syndromes oftener than physicians. In any event, this clinical picture must be a rare one, despite the frequency of dental and periodontal infection.

CONCLUSION

The authors describe 4 cases in male adults. In the first, bilateral facial and a unilateral hypoglossal neuritis occurred as part of a general polyneuropathy which began with "referred cardiac pain." In the second, a bilateral facial neuritis followed thoracic herpes zoster. In the third, bilateral facial neuritis, unilateral tinnitus aurium, and transient diplopia on divergence followed a bilateral uveitis. In the fourth, a paratrigeminal sympathetic paralysis (Horner syndrome), trigeminal pain, and a homolateral uveitis resulted from an ascending infection which began in an alveolar (maxillary) abscess. In none of these cases was there any evidence of heavy-metal intoxication.

In considering these cases and the related literature, a number of interesting facts deserve emphasis. We seem to be dealing with virus infections which are lymph- or blood-borne. Until viruses can be identified with precision it would seem advisable to regard these cases from their clinical viewpoint. In the future, etiological criteria will more effectively define the individual case.

It is curious that the facial nerve is so vulnerable to infection or intoxication. The well-known incidence of Bell's palsy need only be mentioned in this connection. In contradistinc-

tion, the seventh nerve is most resistant to local intracranial pressure, accounting for the mildness of facial involvement in large acoustic neuromata.

The occurrence of uveitis in 2 of the 4 cases is not surprising when one considers the susceptibility of this tract to infections of a general as well as of a local character.

At present, no treatment seems specifically effective. The rapid onset and recovery of these neuritides in the nonfatal cases is in harmony with similar features exhibited by most of the other known virus diseases.

We are indebted to Dr. E. D. Friedman (Case 1), to Dr. Foster Kennedy (Cases 2 and 3) and to Dr. Paul Stewart (Case 4) for permission to use this material from their respective services.

1192 PARK AVE.

SOCIETY FOR THE PREVENTION OF ASPHYXIAL DEATH

The second Annual Conference will be held on February 19th and 20th at the Hotel Biltmore, New York City. Eminent speakers will discuss the problem of death from asphyxiation during the two days from three angles: research, instruction and practice. A dinner in honor of the pioneer in prevention of asphyxial death, the late Dr. Joseph O'Dwyer, will follow on the evening of February 20th. Reservations for the dinner may be made in advance through the office of the Society for the Prevention of Asphyxial Death at 2 East 103rd Street, New York.

The *Southeastern Surgical Congress* will hold its fifth annual assembly in Nashville, Tennessee, March 5, 6, and 7. Secretary: Dr. B. T. Beasley, 1019 Doctors Building, Atlanta, Ga.

Address to County Societies on Venereal Diseases.—Dr. James N. Vander Veer, Liaison Officer between the State Society and the Division of Social Hygiene of the State Department of Health, announces that Dr. Pfeiffer of that Department and Dr. Vander Veer are addressing any of the subjects of "syphilis and management," provided notice in advance to them. Moving picture of the syphilis program which are new and of value.

The American Public Health Association announces that its Sixty-third Annual Meeting will be held in Pasadena, California, September 3 to 6, 1934. The Western Branch of the Association will hold its Fifth Annual Meeting at the same time.

Dr. J. D. Dunshee, Health Officer of Pasadena, has been appointed Chairman of the Local Committee on Arrangements to be assisted by Dr. John L. Pometoy, President, and Dr. W. P. Shepard, Secretary of the Western Branch.

ANXIETY AS A MEDICAL PROBLEM

By SANDOR LORAND, M.D.

*Adjunct Psychiatrist, Mt. Sinai Hospital,
New York City*

Read at the annual meeting of the Medical Society of the State of New York at New York City, April 4, 1933.

In these days of depression when all humanity is burdened with anxiety, it becomes more important than ever to consider the problem of anxiety. Economic difficulties are added to the struggle in the daily routine, and it is to be expected that individuals of weaker psychological make-up react in an exaggerated manner. To the intrapsychic conflicts which may create anxiety, the external economic factors come as additional disturbances. Persons apparently well adjusted, formerly coping with their habitual difficulties, now become unable to make an adjustment.

The manifold aspects of the psychological and social implications of anxiety, are so prominent and so central, that we cannot ignore them when dealing with the sick. It no longer suffices to recognize their presence; we must deal with these anxiety manifestations as part and parcel of the whole illness.

Medical education has hitherto not displayed much interest in the psychological factors of the patient's illness. It did not help matters any, that the physician had more and more opportunity to see among his patients many suffering from mental anguish. In general, the medical treatment was adequate, but sometimes the physician could not explain the absence of the expected improvement. The reason was simple. Because of the lack of interest in the psychological implications which paralleled the physiological difficulties, the physician did not comprehend the patient's difficulties which did not take an organic course. They therefore did not give full attention to those complaints, and fell into the habit of regarding them as unimportant. Feeling their inadequacy to penetrate and to follow the illness along nonbiological lines, they were compelled to give up the further study of the case. Yet, access to the mental aspects of illness, present themselves obviously in the symptom. One has merely to start his investigation with a view of including the total personality.

We may generalize here and say that the outstanding difficulty of every neurotic is the inability to adjust properly to society. This difficulty varies in degree with the severity of the neurosis itself. In anxiety neurosis or

in morbid phobias, the maladjustment to society is not always apparent; nevertheless we are able to obtain the information from the patient that part of all his actions are permeated with anxiety. It takes a large portion of intellectual effort and energy to fight off the anxieties which accompany his actions. In probias, this use of energy is more apparent than in the diffuse anxiety states. To understand the origin of the specific anxiety we have to examine the conflicts which have produced it. These conflicts may yield an understanding of the way the person habitually handled his conflicts which, in turn, may illuminate his personality make-up. The psychic forces which work side by side in synthetic function and those which at other times operate in antagonistic ways, will also reveal themselves at close examination.

By close examination of the psychic forces, which make the person act and react, and which, in turn, determine his behavior and make him a member of society, we finally discover those instincts and impulses which start in early childhood. For a time fully gratified these instincts eventually begin to meet with frustration. Reality, represented by the parents at first, will be a barrier to the full expression of these impulses. Repressive forces come into action. As a result of this, a compromise formation must be attained by the child. He must compromise; he must accept the external demands of reality and give up some of his desires. This compromise formation becomes the prototype for life. The inability to accomplish this invariably leads to conflicts. On the strength of the instinctive desire and on the strength of the power for repression, will depend the degree to which the conflicts incapacitate the individual in his actions. Conflicts may therefore be considered as the result of a struggle between two antagonistic strivings; the instinctive desire which aims at gratification at any cost, and the demands of reality which inhibit the straightforward tendencies for gratification. Of these two forces which exert their dynamic action in all of us, the instinctive desire is usually disguised (it is unconscious) because self-criticism does not let us recognize it in ourselves. If the drive is very powerful, and if there is danger of its breaking through to action, anxiety develops, serving as control.

The question arises: How can we balance these opposing forces? In other words, how can we, on the one hand, modify the instinctive desires from their primitive form, and on the other hand, how can we make reality demands more tolerant?

In order to enable you to follow the theoretical discussion of the problem of conflicts between instinctive drives and reality demands, and in order to make the approach to the origin, the content and the treatment of all anxiety states, more comprehensible, I present the following clinical case

The patient is a man, 35 years old, of good social standing and with business ability. He had been married for thirteen years, and has two children.

The peculiar complaints and fears with which he came for treatment sounded childish and much like a fairy tale. He himself considered them so, but he could not prevent their appearance or escape their torture. Out standing among these fears was an animal phobia. He feared the possibility of people, and of himself, turning into animals.

He also was afraid that he might go blind. He feared that people would disintegrate. He had to repeat his name often so as to remember who he was. Besides, he was afraid that he would not be able to recognize people.

In tracing back his life history and his developmental stages, strong aggressive tendencies became evident. He felt at times great irritation with his family despite the tenderness and devotion he lavishly showed them. He would not hurt their feelings, but underneath this superstructure of tenderness, he was constantly annoyed.

His ambivalent feelings manifested themselves also in his sexual life. He suffered from ejaculatory praecox, which, in addition to his anxieties, was another reason to seek aid.

The patient's sickness dated from the year following his marriage. It started with the fear that his heart would stop beating (several members of the family having died of heart disease). Frequent medical care consisting of reassurance only, gradually caused this fear to disappear temporarily, but the anxieties started anew a few years later.

As we retrace his development from early childhood, we see him as the only child, sometimes alone with his mother for days at a time, listening to fairy tales. The occasional quarrelsome and aggressive behavior of the father also played an important role in the patient's anxiety. After a long-lasting analysis, all the symptoms showed themselves to be revived and reactivated episodes of his forgotten childhood.

It is a well-known fact, as was the case with this patient, that at the bottom of the childhood fears is the desire for attention, a desire to be taken care of, not to be left alone, etc. Our patient also developed his anxiety symptoms for the purpose of protection.

All during the years of his marriage the patient secretly contemplated extra-marital sexual experience, not having had any before marriage. His fantasies when walking in the street, or when in company, carried him always into imaginary situations involving other women. Those fantasies ran parallel to fantasies about some day divorcing his wife, and again being independent. With the birth of his first child, the initial symptoms and fear of blindness developed. He became more concerned with himself than with external matters. And from then on, with the persistent craving for extra marital gratification there always appeared some kind of fear concerning his health. His anxieties served to divert his sexual interests, thus avoiding the probable dangers which might otherwise have arisen from their gratification. These imaginary dangers were also bound up with his childhood fears of his father, whose criticism he had always dreaded. He had remained infantile in many of his reactions. His early childhood experiences, the over protective attitude of his parents and pampering by his mother, influenced him in later life by constantly making him expect compensation for all his accomplishments.

In maturity, we consider the fear of being left alone a neurotic one, because the adult is expected to tolerate frustration. Neurotic people cannot rid themselves of early childhood attachment, they do not develop enough resistance and defense against the vicissitudes of life. They cannot and do not achieve the complete management of instinctive drives which is important in adult adjustment.

Instinctive drives are mobile in all of us. The ego registers every attempt of the socially inhibited instinctive drive to break through; it declares the drive dangerous, and projects it outward, attaches to an external situation or object, thus creating and maintaining a state of anxiety.

One point must be emphasized. Namely, that whereas, normally, we differentiate between real anxiety and neurotic anxiety, for the neurotic, his anxiety or phobia constitutes a real danger. To be sure, the danger is not an outer, imminent one, as in the case of real anxiety, from which we try to escape, but it is an inner danger, a fear of the strong urges of an instinctive desire.

The importance of the quantitative elements

in creating anxiety, should also be emphasized. Qualitatively, all of us normally have anxieties in a minimized degree. The difference between neurotics and healthy people is determined by the quantity of the emotions which have to be dealt with and the measure of the anxiety which is produced.

It is clear from the above consideration, that in all methods of therapy, we must keep in mind that neurotic tension and anxiety is caused by strong instinctive drives and desires. To provide relief for these desires and to make gratification possible, at least in some measure, is the task of therapy. Instinctive desires may be transformed into acceptable reality expression, if properly recognized and if the person learns not to fear them.

The classical method of accomplishing this is psychoanalysis, which, in its methodological approach, intends to reorganize the forces in action and endeavors to transform the neurotic personality into a stable, self-reliant being.

I shall not discuss the details of the psychoanalytic method of treatment. I shall merely mention that a great amount of energy formerly wasted by the patient in his battle with himself to keep his urges in repression and to make himself fit to social demands will be utilized after analysis in a more healthy way. New objects of interest will be created and the outside world will be invested with love and interest which formerly was centered on the patient himself.

But even in a daily routine medical practice, the physician can help a great deal. If, for reasons, analysis is impossible, a partial solution of the patient's problem may be brought about and he may be adjusted to a healthier mode of living.

In order to accomplish the task of helping the patient in his distress, the first thing is to utilize and to take advantage of the trust and reliance with which every patient approaches his physician. We can even put it more decisively and say that every patient, and especially the one suffering from morbid anxieties, behaves like a child and looks upon the physician as a parent from whom he expects help and guidance. I think that in no situation including patient and physician, does the child-parent relationship show itself more clearly than in anxiety neuroses. In this child-parent relationship lies the hint of where the physician will have to look for the root of all anxieties.

To understand the patient's distress, it becomes necessary to know the patient's whole life, his family and social relationship, and more

than that, to examine, after getting his confidence, his most hidden thoughts and wishes, mostly those which he considers antisocial. Following that line, the sexual implications will be found of primary importance in the creation and maintenance of the anxiety state. The patient, having gained knowledge of and insight into his conflict, the next task will be to induce a milder attitude toward himself and his hitherto repressed desires. He will have to learn to accept them as his own.

I make it a practice to use the above methods of approach in the Mental Hygiene Clinic where the use of classical analytic therapy is not possible. At the Clinic, we see patients who suffer from different anxiety states over a protracted period of time. We discuss the patients' problems, and reassure them with suggestions. More than that, I, at times, even apply hypnotic suggestion, knowing that the effect of hypnosis is only temporary, but if a temporary improvement is induced, there is already a good working basis for the future. We bear in mind that hypnotic suggestion really takes full advantage of the patient's unconscious dependence on a parental substitute, but since the aim of treatment is to relieve the patient of distress, this method serves the purpose. Other methods can be utilized, provided one knows what he is doing.

A certain degree of anxiety must be present normally, to achieve adjustment to the demands of reality. We must also be able to renounce without great pain and suffering, those of our desires, which, if gratified, would be the source of discomfort in our social life. Normalcy requires a certain amount of elasticity. If the individual is too weak to combat his too strong instinctive tendencies, he either oversteps the normal boundaries of society, or becomes neurotic. He will exaggerate the anxieties, will become panicky, and he will consume all his energies in combating fears instead of using them for social purposes.

In concluding my rather sketchy theoretical considerations and case history, let me remind you that the present mode of approach to the understanding of the symptomatology of all neuroses began with Freud's attempt to influence hysterical symptoms which were bound up with anxiety states. This undertaking prepared the way to the deeper investigations into the causation of the neurosis, which led to a new concept of the whole human personality. Anxiety hysterics are understood more easily than any other neurosis, because of the obvious presence of anxiety in all of us. They are also more amenable to therapy if properly understood and approached as a real problem and not as an imaginary one.

115 EAST 86TH STREET.

COLLOIDAL CHEMISTRY AND PSYCHIATRY

By H. BECKETT LANG, M.B., F.A.C.P.

*Director of Clinical Psychiatry, Marcy State Hospital,
Marcy, New York*

Read at the annual meeting of the Medical Society of the State of New York, New York City, April 4, 1933

It is of interest that biochemistry is endeavoring to explain physiological activity of the living organism by the study of cellular function. There is by no means agreement in observation or interpretation of the results of the various studies.

In the last few years there have appeared new biochemical hypotheses concerning colloidal states related to cell function. Many of these are still debatable and controversial.

Briefly, the various theories advanced concern themselves with the wide variety of cellular functions. The question of cell permeability is discussed, some criticizing the conception of a semipermeable membrane, others asserting its presence but considering the process of diffusion within the cell to be dependent on the activity of the cellular colloids.

Again there is controversy as to the mechanics of water intake and excretion within the living cell. Some views hold that osmotic forces are responsible. Others consider that the influence of the hydrogen ion concentration, size and shape of the colloid particle, and variation in the electrical charge are the reasons for the increase or decrease of water within the cell.

Other studies are those relating to hydrogen ion concentration, oxidation-reduction capacity, and to the concept that the cell protoplasm consists of matter predominantly protein in a physical state described as colloidal dispersion.

Literature has been accumulating, endeavoring to explain disease symptoms by theories of altered colloidal states. Some of them have even been stated as being the whole cause of the disease. It would have been much wiser if they had been kept within proper bounds and used as suggestive explanations and not as conclusions that colloidal activity might be the basis of altered function.

Ultramicroscopic studies of excised brain tissue seemed to show variation in the response of the observed tissue to changes under the influence of different chemicals. With potassium, iodide, chloride, acetate, or sulfate, swelling occurred, descending in degree from the first to the last. Less swelling

was obtained when the various chlorides of potassium, sodium, calcium, or magnesium were used. The cell structure showed loss of normal swelling with aluminum chloride. The offered explanation of this was that the colloid particles varied their capacity to take up and give off water as the absorbed electrolytes varied. Using hypertonic and hypotonic solutions, cell swelling and shrinking was also reported. Demonstration of this in excised tissue may be so but it does not indicate that such necessarily occurs in the living functioning organism.

Another theory concerning proteins of the blood plasma and their relationship to disease is: that these blood proteins are in a state of defined normal dispersion; that this normal state is altered by invading microorganisms or chemical toxins, so that water is either lost by the protein particle, or the normal electrical charge is altered. Either of these alterations, it is considered, will then result either in aggregation or dispersion of the protein colloids.

This theory has been used as an explanation of convulsive phenomena. The contention is that in rapid hydration the protein particles are precipitated in the pericapillary spaces of the brain and in slow chronic hydration they collect in the capillaries, thus causing increased cell irritability and so convulsions.

More conservative and particularly concerning convulsive states in uremia and epilepsy are those of Foster' and McQuarrie'. Foster in discussing metabolic states and uremia comments on the relationship of excess chlorides and water retention. He suggests that the hydrogen ion concentration has a function in determining whether the excess chloride will be in the plasma or in the cell. If it is in the cell, then cell swelling with changed function appears. He goes on to consider that cell-oxygen deprivation produces cellular acidosis and as a result cell edema occurs, and that this is a colloid change. Such cell acidosis would be enhanced when the phosphorus balance and ammonia formation were lowered. He finally suggested that convulsive uremia might be combined with a specific toxic base with a nitrogen retention and that the toxic base might be in the nature of a reversed chemi-

cal reaction of a substance that normally was excreted.

McQuarrie⁷ showed in epileptic children that sudden increased water intake without diuresis resulted in convulsive seizures but negative water balance produced cessation. Sodium excretion predominated during this seizure preperiod and potassium during the convulsive period. The increased potassium output appeared from 12 to 36 hours prior to the convulsions.

He also showed an increased excretion of sodium and chloride during diuresis. This he considered indicated a removal of extracellular fluid. During his exhibition of pitressin he obtained an increased potassium excretion, and in the postpitressin period the excreted minerals were potassium and chloride instead of sodium and chloride. He interpreted this as a "leakage" of the potassium from within the cell and diffusing into the extracellular fluid.

He suggested from these observations that water retention with low mineral content acted so that excess water would tend to enter the cell and for the intracellular contents to diffuse out. He considers, as a tentative explanation, that in epileptics there is a low limit of protection against this water variation and that the influence on the cell may be due to inherent abnormalities of the cell membrane or the cell colloids. He also suggested that increased cell irritability might be due to this disturbed equilibrium between the various electrolytes and the hydrated cell colloids.

These studies seem to suggest a possible theoretical consideration that in convulsive phenomena there may be a disturbance at the physicochemical level which consists of a periodic variation in the normal ionic milieu, increased water retention in the cell, deficient excretion of metabolic products, and alteration in normal dispersion. The observations do not indicate or conclude that such disturbances are the principal or basic causes of convulsions.

Recently the theories of Bancroft and his associates have received wide notice.

Bancroft¹ advanced a theory of anesthesia and narcosis based on the assumption that the brain tissue cells exist in a state of colloidal dispersion.

He reported a series of observations of experiments using egg white albumin sol as a substrate. This was subjected to the action of a variety of anesthetics and narcotic drugs. The resulting behavior he described as coagulation, which in the presence of other drugs was altered to a condition he described

as peptization. Then, in experiments with animals, he considered that he could demonstrate a reduction of the anesthetic action by these peptizing agents. His conclusions were that reversible coagulation produced or accompanied anesthesia, also that decreased colloidal stability produced increased cell irritability up to the point of coagulation after which depressed cell function occurred. He explained the irritability present at one stage in recovery from anesthetics as due to reversibility of the agglomerated colloids to a state of normal dispersion.

Handovsky² offers a different explanation as to the influence on cell activity by narcotic drugs. His hypothesis is also based on the dispersed state of the cell colloids, but he concludes that narcotization produces decreased dispersion and depression of activity, whereas increased cellular activity occurs with an increase in colloidal dispersion.

Quastel³ offers an entirely different theory as to the action of narcotic drugs. He has shown that they inhibit the carbohydrate metabolism of the cell. They do this by preventing the oxidation of lactic and pyruvic acid. These narcotics do not prevent the cell taking up oxygen nor the brain catalysts activating such oxygen. This disturbed metabolism, he considers, depresses cell function. Based on this, he has administered glucose and insulin during prolonged exhibition of narcotics, so preventing ketonuria and other toxic symptoms. He states that the results were favorable but he has not yet published these.

Bancroft¹ has further postulated that there could be two forms of "insanity"—one agglomerated, associated with overactivity, the other overdispersed or peptized, associated with decreased activity. He has quoted, in support of his contentions, examples of mental reactions in cases receiving drugs, which he defines either as coagulating or dispersing. He then concluded that these examples were "definite proof of the view that there is a normal state of dispersion of the nerve colloids and that any alteration from this state will bring about abnormal mental reactions."

In another conclusion he suggested that "disorders of overdispersion may be benefited by coagulating agents and disorders of decreased dispersion would be improved by peptizing agents."

From another series of experiments, both *in vitro* and with animals, he concluded that sodium amytal was a good example of his defined agglomerating drug and sodium thiocyanate an equally useful peptizing agent.

Observations were made on the exhibition of these two drugs in cases of manic-depressive and dementia praecox psychoses. These observations seemed to show that in these psychoses there appeared to be an opposite response to these two drugs. The responses were described as either improvement in behavior or the opposite.

Further, using Bancroft's theories and definitions, a conclusion was drawn that the manic depressive cases were correlated with agglomeration of the cell colloids, and the dementia praecox with overdispersion. The altered behavior was present only during the exhibition of the drugs and did not constitute a clinical improvement either in behavior or mental content.

This report is open to severe criticism as to the lack of proper controls and insufficient length of time in observation. Moreover, allowance was not made as to the possibility of individual idiosyncrasy to the drugs, so that the positive or negative behavior reported as evidence of the drug reactions might have been different if a wider range of dosage had been used.

Harris and Katz⁴ in their study did not obtain any such opposing results, but did find some serious toxic disturbances consequent to the use of sodium thiocyanate.

Further studies were made with these two drugs, both orally and intravenously. With sodium amytal orally, it was found in some cases of dementia praecox catatonia and manic-depressive stupors that individual variable amounts would allow a brief period of contact with the patient, so that information as to the mental content could be obtained. Such states were only temporary during administration of the sodium amytal and cannot be considered in any way a clinical improvement. When increased doses were given, sedation was invariably obtained irrespective of the diagnosis or of the type of behavior.

Moreover, sodium amytal has been used to produce prolonged narcosis in states of excitement occurring in either manic-depressive or dementia praecox cases. With the manic-depressives, much improvement was obtained, whereas with the dementia praecox group, the excitement was allayed, but the trend and behavior in response to it was not altered. This is contrary to Bancroft's theory, as he contended that the manic-depressive group was of the agglomerated type and it was found that his defined agglomerating drugs produced eventual improvement, whereas with his described peptized group, no results were obtained with his so called agglomerating drugs.

In a more recent observation, 11 cases of dementia praecox—9 hebephrenic and 2 paranoid—were studied under sodium thiocyanate. They all showed chronically excited states. Under sodium bromide, 9 showed control of excitement and improved response to nursing care, but very little reaction when under sodium barbitol. Four cases were helped by sodium bromide but were more responsive to sodium barbitol. One was slightly improved by sodium bromide and showed no response to sodium barbitol.

These 11 cases would fall in Bancroft's classification of the overdispersed type. But it was found that a peptizing agent produced benefit, whereas an agglomerating agent, which according to his theory was indicated, did not do so.

Bancroft states that sodium bromide and sodium thiocyanate have similar peptizing action and that sodium thiocyanate is the better of the two. Because of the improvement to sodium bromide, the 14 cases were given sodium thiocyanate. One dementia praecox hebephrenic was apparently improved in behavior and has continued improved, even with the cessation of the drug. Her trend, however, has not shown any alteration. The remaining 13 were very much excited, 7 cases showing signs of mild intoxication. Following withdrawal of the sodium thiocyanate, they continued excited and did not show improvement until sodium bromide therapy was resumed.

From these subsequent observations the conclusions of the first report as to correlation with theoretical colloidal states are in error.

These later studies, moreover, have not shown any general therapeutic value for sodium thiocyanate in the treatment of the psychoses.

From the clinical studies there is no evidence to show that such colloidal states as Bancroft describes are present in the psychoses. No work has been done to show that sodium amytal and sodium thiocyanate act specifically and selectively on the sensory cells of the central nervous system, nor is there evidence that the action of these drugs in the body is essentially colloidal as Bancroft considers.

Because a drug defined as agglomerating produces improvement in a psychotic state, it cannot be concluded that such psychotic state was due to an overdispersion of the brain colloids. Similarly no conclusion can be reached that agglomeration is the colloidal state present if a so called peptizing drug produces benefit.

Clinical experience has now shown that in response to these so-called agglomerating and peptizing drugs there is no relation between the reaction and diagnostic classification.

In conclusion it may be said that biochemistry is attempting to explain cellular physiology and nerve-cell function in terms of colloidal behavior. Explanations have also been offered for pathological disturbances. The theories are of interest and it is hoped will be of assistance in the solution of some of our problems. However, in their present hypothetical and inconclusive state they cannot be accepted as the adequately correct explanation of psychotic symptoms and syndromes.

MARCY STATE HOSPITAL.

THIS AND THAT

Immediate and united effort to curb the rapidly rising death toll from degenerative diseases of the heart, arteries, and kidneys was urged by Dr. William Muhlberg, medical director of the Union Central Life Insurance Company of Cincinnati, at the recent convention of life insurance presidents. He said that for the first ten months of 1933, as compared with the like period of 1932, deaths from these causes showed an increase of 10.6 per 100,000 population.

A native East Indian medical journal reaching this office carries a full-page advertisement of a charm that "secures employment to the unemployed," gives "success in law-suits," "realization of your fondest dreams of love and marriage," "victory over enemies," "sure relief in chronic diseases," and "body-guard against dangers, accidents, witchcraft, etc." The price varies with the number of the above items covered by the charm, ranging from \$10. to \$50.

Landlords of apartment houses in San Francisco are offering free medical, surgical and hospital service to tenants who pay their rent in full on the date when due.

A medical writer in Kansas, disgusted with the medical ballyhoo he hears on his radio, remarks wearily that "the day may come, and soon we hope, when one can sit by his radio and get a genuine and continuous thrill of Wagnerian opera without being interrupted by a radio announcer who tells the audience of the air what it should take to make its bowels move."

An interesting plan is being tried out in a Mormon settlement in Western Canada. The town has about 2,000 people, who have voted to pay the two local doctors \$25 a year for each family, and in return the doctors guarantee complete medical and surgical care, even including major operations. Each physician receives about \$3,750 a year under this plan, beside occasional fees for treating families who do not join. The doctors and townspeople thus are both relieved of worry over unpaid bills. How the scheme would work in a larger community is, of course, another question.

The distress of some doctors in Great Britain is revealed in the report of an insurance company which had on its books 78 cases of panel doctors who had assigned panel fees amounting to \$175,000 a year to money-lenders. The money-lenders, in this way, secured an influence in the administration of medical benefit, not always used for the highest ends. An insurance committee is looking into the matter for further action.

A lot has been said about the falling death rate during the depression, but now another part of the picture appears. The Milbank Fund, in a survey of 514 children in a poor New York neighborhood, find that 40 per cent are undernourished. It is not necessary to tell the readers of this journal what that means in the way of future debility and propensity to illness among these starvelings. Here is a future health problem ready right now for preventive treatment.

NEUROLOGICAL AND MENTAL SYMPTOMS OF PERNICIOUS ANEMIA

By EDWARD LIVINGSTON HUNT, M.D.
New York City

Read at the Annual Meeting of the Medical Society of the State of New York at New York City, April 4, 1933.

In order to understand the *neurological and mental symptoms* of pernicious anemia one must understand the disease and its pathology.

It is incorrectly described as a systemic disease; it should be described as a "three-system disease": that is, one which involves three different systems, the blood, the digestive, and the nervous. The percentage of involvement of these three systems, varies; nervous symptoms occur in 80 per cent; blood changes in 90 per cent, and digestive symptoms in almost 100 per cent. In the 80 per cent in which the nervous symptoms appear the changes involve all three parts of the nervous system—brain, cord, and periphery.

The *pathology* of the disease is briefly as follows:

The cord is white, shining, enlarged, and swollen. The typical lesion is one of degeneration. It begins with small patches in the white matter of the cord, which extend and coalesce. These patches may extend upward, downward, or, as is more likely, may assume an annular form. Collier considers that the annular type of degeneration is the more frequent and the more characteristic. Several of these patches may coalesce, destroy the cord, and form cavities. In addition there occur secondary degeneration of the white columns, and retrograde changes in the cells of Clarke's columns.

These patches of degeneration are not limited to the cord, but they also invade the medullary substance of the cortex of the brain; here they are smaller, more scattered, and less likely to coalesce. In the brain there are also found small areas of edema, degeneration of the pyramidal cells, and minute hemorrhages.

In the peripheral nervous system the changes consist of swelling of the medullary sheaths followed by degeneration and disappearance of the axis cylinders.

From this it is evident that the neurological symptoms depend upon two factors: (1) the distribution, and (2) the extent of the pathological changes. Since the disease is chronic, of long standing, and from time to time tends to progress, the clinical symptoms vary. Because all three parts of the nervous system are involved, the picture appears confused and bizarre.

The neurological symptoms are of two kinds: sensory and motor. The sensory can best be divided into two headings, subjective and objective. The subjective are: tingling, numbness, burning, cramps, soreness, coldness, twisting, band, dead, and girdle sensations. The objective are loss of deep sensibility, loss of joint sense, loss of vibratory sense, astereognosis, and hypesthesia. The sensory symptoms are the more characteristic of the two. They are more frequent, appear earlier, and are of more prognostic and diagnostic value than are the motor; they may be slight or severe: they may appear early or late.

The motor symptoms occur less frequently, appear later and progress more slowly than do the sensory. They consist of weakness, ataxia, and mild or severe paralysis and paraplegia.

While ataxia and weakness are common in the early stages of the disease, paraplegia is, undoubtedly, the most frequent motor symptom, especially, in the later stages. It may occur early; it may be flaccid, spastic, or ataxic. It may affect the arms, or legs, or both. It is usually insidious in onset, gradual in development, and unless arrested, steady in progress. It may remain stationary, it may improve, or it may progress to a condition of complete paralysis.

In unusual instances the motor symptoms precede the sensory and the arms weaken before the legs. In still rarer instances the paralysis may involve the trunk or some of the viscera.

The reflexes in pernicious anemia vary according to the stage of the disease; there is first the irritative form, later the paralytic. At the beginning one column may be involved; later two or more. When the disease is well established, the pathological changes assume the characteristic "annular configuration" which results in an almost complete transverse lesion of the cord. Thus pernicious anemia may present a picture of tabes, of lateral sclerosis, of a transverse myelitis, or as a result of changes in the peripheral system it may simulate the symptoms of multiple neuritis.

The knee jerks therefore may take any form; they may be present, hyperactive, markedly exaggerated, diminished, absent, or unequal; they may vary from time to time. They may reappear after being lost, due, first, to an involvement of the posterior columns and later to an involvement of the lateral columns.

The Babinski reflex is often present, owing to an involvement of the pyramidal tracts.

An important and interesting question which always arises in pernicious anemia, and one to which not enough attention has been given, concerns the relationship of the nervous symptoms to the changes in the blood. It may be stated as a fact, to which all authorities subscribe, that one of the four conditions may exist.

(1) The blood changes may precede those of the nervous system.

(2) The nervous changes may precede those of the blood.

(3) The two may appear at the same time.

(4) The blood changes may appear very late or not at all.

I should like to emphasize the fact that nervous symptoms, either motor or sensory, may, and often do, appear long before the blood gives any indications of the disease; therefore, many patients who complain of paresthesia in the extremities, and especially in the legs should be considered as tentative cases of pernicious anemia.

A diagnosis of pernicious anemia from the nervous symptoms, is difficult. It resembles syphilis in that it tends to mimic other diseases, and presents many syndromes. On the other hand, it differs from syphilis in that the nervous system is involved in 80 per cent, whereas in syphilis severe nervous signs appear in about 10 per cent.

In pernicious anemia the nervous system is more apt to be involved in the elderly than in the young. It is also more apt to be involved in certain families than in others.

MENTAL SYMPTOMS

Mental symptoms are common in pernicious anemia.

Cabot reported psychoses in 16 per cent, Wisenberg definite psychotic changes in 40 per cent. Barrett found 33 per cent of the ambulatory cases abnormal, and the Mayo Clinic stated that "mental changes are very striking."

These mental changes are of two kinds: those which occur early in the disease, and those which occur late.

The early mental changes, which may precede all other symptoms, are apathy, indolence, abnormalities of conduct, indifference, and a definite lessening of the capacity for work. Later, the mental changes assume a more definite form; the patient may develop any type of psychosis from melancholia to mania or dementia.

There is no psychosis characteristic of the disease; in the older patients the senile type

is common, with attendant symptoms of confusion, loss of memory, and violence. The most usual form is the so-called paranoid type. The interesting point about the paranoid symptoms is their resemblance to the toxic psychoses. Barrett in making a study of the delusions concluded that they were similar to those occurring in exhaustion and toxic cases and, therefore, assumed that the etiological factor was toxic. The question which then arises is whether these mental symptoms are due to pathological changes in the brain or to the toxins generated by the disease. This question is open to argument. If the mental symptoms in pernicious anemia are temporary and apt to yield to treatment, the conclusion must be that they are the results of ischemia and toxicity, rather than to degenerative changes. Another point to consider, as Weil has pointed out, is, that the early and superficial lesions of toxemia and ischemia, if left alone, may result in pathological changes. This viewpoint is strengthened by the frequency with which the delirium appears. Cabot found it in 44 per cent.

Still other authorities insist on the existence of cerebral lesions as the etiological factor, but they are unable to explain the tendency of many of the cerebral symptoms to disappear under treatment.

The frequency and the variability of the mental changes which characterize this disease causes pernicious anemia to assume importance, from a medicolegal point of view. Hulett reports the case of a patient who developed a paranoid state with delusions of persecution directed against a devoted daughter. This patient disinherited the daughter, who brought suit to break the will and succeeded because of the medical testimony, which proved that patients with pernicious anemia are subject to mental aberrations. Other authorities cite cases in which the patient became brutal to his wife and stole without any memory of the facts.

In conclusion I want to emphasize five points.

(1) That pernicious anemia is a three-system disease.

(2) That any of the three systems may be involved first.

(3) That the neurological symptoms of pernicious anemia are both motor and sensory.

(4) That mental symptoms are frequent and varied.

(5) That the cause of the mental symptoms is open to argument; it may result from pathological changes in the cortex and other parts of the brain; it may result from toxemia.

THE INFLUENCE OF NATURAL CARBONATED MINERAL WATER BATHS
ON BLOOD PRESSURE AND PULSATION

WALTER S. McCLELLAN, M.D., ERIC F. JOSLIN, M.D., and
GRACE V. MAGUIRE, M.D.

*From the Medical Department of the
State Reservation, Saratoga Springs*

The evaluation of any method of treatment is based in a large measure on the clinical results obtained by the use of the treatment. No extensive clinical study has been reported in this country regarding the value of balneotherapy. The following question is generally raised when balneotherapy is mentioned "What is the clinical effect of a series of baths on the patient who receives this treatment?" In order to answer this question with some degree of accuracy it is necessary to make long and detailed clinical observations of a large number of patients who are taking the treatments.

There are, of course, many reports in the literature regarding the influence of the famous natural carbonated baths in Europe. It is impossible to say without careful studies that the same results may be expected with the waters here as are obtained abroad and it becomes necessary to make our own observations in order to answer the question which is so commonly asked. The material on which this report has been based, was a group of 102 patients who received series of baths during the summer of 1932 at the State Reservation Bath Houses at Saratoga Springs. The patients were under the care of local physicians who directed their course of treatment during their stay in Saratoga. The treatments were mainly mineral water baths, using the natural mineral water from the Lincoln Springs which is supersaturated with carbon dioxide. The observations of the blood pressure and pulse were made by the authors during this period. The review of this material points out the course which may be followed in studies of this type. In the small series to be reported, of course, no final or general conclusion may be drawn, but the consistency with which certain changes were ob-

served will be shown in the report of the summary of this work.

Sex and Age Distribution—Of the 102 patients who were observed during the summer, 11 were males and 61 females. In Table I is presented the distribution of this group as regards age. It will be seen that over 40 per cent were in the decade between 50 and 59 years. This is an average group of patients who come for treatment and shows the age when people feel the necessity for treatment of this type.

Clinical Diagnosis—In the group chosen for these studies 66 patients, or 64.7 per cent of the total, had some primary cardiac or circulatory disorder. The relatively high percentage of this type is due to the fact that the patients selected for the study were mainly those receiving the Saratoga cardiac therapy and that our studies dealt primarily with blood pressure variations. In a general survey of the patients who come to Saratoga for treatment, approximately 30 per cent are classified as cardiac patients. The remaining 36 patients selected for this study included 18 with arthritis, 5 with urinary disorders, 4 with chronic gallbladder disease, 1 with obesity, 3 with diabetes, and 2 with other conditions.

Blood Pressure—An analysis of the records of 88 patients for whom detailed data regarding variations in blood pressure were obtained revealed that the systolic blood pressure at the beginning of treatment was under 120 mm Hg in only 9 patients of the group, while 52 patients, approximately 60 per cent, had blood pressures above 150 mm Hg, and 21 of these 52 were in excess of 200 mm Hg at the start of their cure.

TABLE 2—A COMPARISON OF THE CHANGES OF SYSTOLIC AND DIASTOLIC BLOOD PRESSURES TAKEN AT THE BEGINNING AND END OF THE TREATMENT

Changes in pressure	Systolic		Diastolic	
	Num-ber	Per-cent	Num-ber	Per-cent
+11 to +30 mm Hg	11	12.5	5	5.7
+10 to +10 mm Hg	43	48.8	42	73.9
+11 to +30 mm Hg	27	30.7	17	19.3
-11 or more mm Hg	7	8.0	1	1.1
Total	88	100.0	88	100.0

The changes in their systolic and diastolic pressures were followed during the course of treatment. Studies of the blood pressures

TABLE 1—AGE DISTRIBUTION BY DECADES OF THE PATIENTS OBSERVED

Age distribution	Male	Female	Total
Under 20	2	0	2
20-29	1	0	1
30-39	5	5	10
40-49	10	7	17
50-59	12	29	41
60-69	9	7	16
70 or over	2	2	4
Not recorded	0	11	11
Total	51	51	102

were carried out in the following manner: the patients undergoing treatment came to the baths in the morning and were allowed to rest for 15 to 30 minutes before taking the initial blood pressure. Then they took the bath as prescribed by their physician and following the bath rested for a period which varied from 30 to 60 minutes. The second blood pressure reading of the day was taken at the end of this rest period. In this way we obtained a series of blood pressure readings taken before and after the bath. The material presented in Table 2 deals with changes which occurred during the course of treatment and not with the individual bath; it includes a brief summary showing the number of patients and the percentage of the total number classified on the basis of variations which occurred in their systolic and diastolic pressures. In this series, approximately 39 per cent showed a reduction in their systolic pressures of 11 or more mm. Hg, and approximately 20 per cent showed a similar change in their diastolic pressures. This analysis includes the whole series observed, regardless of whether their blood pressures were elevated at the beginning of the course or not.

TABLE 3.—AN ANALYSIS OF THE VARIATION IN BLOOD PRESSURE OF THE PATIENTS WHOSE SYSTOLIC BLOOD PRESSURE AT THE BEGINNING WAS 150 MM.Hg OR OVER

Systolic pressure at beginning	150-199		200+		Total	
	Num-ber	Per-cent	Num-ber	Per-cent	Num-ber	Per-cent
+11 to +30 mm. Hg	3	10.7	3	12.5	6	11.5
+10 to -10 mm. Hg	10	35.7	9	37.5	19	36.5
-11 to -30 mm. Hg	11	39.3	9	37.5	20	38.5
-31 or more mm. Hg	4	14.3	3	12.5	7	13.5
Total	28	100.0	24	100.0	52	100.0

A more detailed analysis was made of the variations in blood pressure during the course of treatment of that group with systolic pressures above 150 mm. Hg at the start of the treatment. In Table 3 the patients are classified on the basis of the systolic blood pressure at the beginning of the course and divided into two groups: those with blood pressures between 150 and 199 mm. Hg, and those with pressures of 200 mm. Hg or over. Variations of less than plus or minus 10 mm. Hg were held to be without any definite significance. It may be seen from the table that 38.5 per cent of the patients showed a reduction in their systolic blood pressure of between 11 and 30 mm. Hg and that 13.5 per cent showed a reduction of 31 or more mm. Hg. Therefore, on the basis of this analysis, we found what may be considered definite reductions in blood pressure of 52 per cent of the patients studied. On the other hand, 6

patients, or 11.5 per cent, showed an elevation during the course of treatment. When we consider the data for the patients with moderate increases in blood pressure, 150 to 199 mm. Hg, as compared with those over 200 mm. Hg, we find relatively little difference in the percentage of patients showing definite improvement.

A consideration of the changes in blood pressure in relation to the number of baths taken in the series showed that 4 out of the 6 patients in whom a definite elevation occurred during the treatment received less than 10 baths in their course, while 17 of the 27 who had a definite reduction in blood pressure took 10 or more baths. The data regarding the number of baths taken in the course are not sufficient to reach any definite conclusions but there is the suggestion that for the most consistent results, the patient should have a series consisting of more than 10 baths.

Other factors which must be considered in relation to the changes reported are the amount of carbon dioxide in the bath, the duration and the temperature. Information available for this series does not provide a basis for comparison of different temperatures or different lengths of time in the baths because nearly all the patients studied took baths between 92° and 96° F. and on the average remained in the tub from 12 to 15 minutes. The question of the amount of gas in the water, which may be varied, depends on the condition of the patient. It was found that 23 out of the 27 patients who showed definite reduction in their blood pressure took baths containing more than half of the effective supersaturation of the carbon dioxide, while those patients who showed an increase in their blood pressure took consistently less than half the effective supersaturation. The question of the best amount of gas in the water to obtain the desired results depends on many other features than just the variation of blood pressure and it must be prescribed on the basis of the general condition of the patient. From the information at hand, however, it appears that better results may be expected with the relatively higher gas content in the water.

Influence of the Individual Bath on Blood Pressure.—In the analysis of the individual bath on the blood pressure, a calculation of the average of the differences between the systolic blood pressures taken daily before and after the bath was made for 66 patients. It was found that 51 of these 66 patients showed a reduction in blood pressure which varied in the group studied from 1 to 20

mm. Hg, while 15 showed increases in blood pressure which varied from 1 to 10 mm. Hg. On the basis of our method of study it is impossible to say that these changes are directly the result of the bath because it is common knowledge that a period of rest may result in some reduction in blood pressure. The longer period of rest which the patient had before the final blood pressure reading may account in part for these findings. It is only possible to say that the bath and the rest period following it resulted in a daily fall of blood pressure in 77 per cent of this group of patients.

Pulse Rate.—The pulse rate was observed in this system of treatment before, during and after the bath. The material to be presented is divided into two types. In the first, the pulse rate at the beginning and end of the whole cure has been compared on the basis of the pulse rates observed after the

minute, which was considered within the normal variation; 19 patients showed a reduction in pulse rate of 6 or more beats per minute. Again as was explained in connection with the variation in blood pressure, this reduction in pulse so generally observed may have been associated in part with the period of rest which followed the bath. However, the relaxation and beneficial rest are favorably influenced by the action of the carbon dioxide during their period in the bath.

Summary

It has been pointed out that the variations in pulse and blood pressure as reported above were a series of observations made during the course of a regular spa treatment. This course included the mineral water bath with subsequent rest period, absence from home, and regular living. The treatments were associated also with drinking of the mineral water. The natural carbonated mineral water bath has certain influences on circulation. It produces a peripheral dilatation of smaller blood vessels with consequent increase of the amount of blood in the area adjacent to the skin. This effect is due to the action of the carbon dioxide either directly following absorption through the skin or indirectly by producing nervous reflexes or both.

The results obtained appear to be a regulatory effect most likely produced through the autonomic nervous system. An elevated blood pressure may be due to an overactivity of the sympathetic division of the autonomic nervous system or to an underactivity of the parasympathetic division. In either case it leads to an unbalance of the sympathetic-parasympathetic systems with resultant predominance of the sympathetic division, which gives rise to the increased pressure. Tachycardia may also occur. If the action of these baths is vagotonic, as claimed by various writers abroad, then the results reported can be interpreted as a return toward normal of this sympathetic-parasympathetic balance. A conception of this nature would explain the reduction in blood pressure, the slowing of the pulse rate and general improvement of cardiac function, which was observed in many patients.

The impression was gained by the authors in the observations on these patients that the improvement was most noticeable in the patients where some nervous influence could account for the increased blood pressure. In contrast, where sclerosis of the arteries was present, the blood pressure remains above

TABLE 4.—A COMPARISON OF THE VARIATIONS BETWEEN THE RESTING PULSE TAKEN AT THE BEGINNING AND END OF THE CURE.

Systolic blood pressure changes in pulse rate	Under 150		Over 150		Both	
	Num ber	Per cent	Num ber	Per cent	Num ber	Per cent
+16 or more	2	5.6	1	1.9	3	3.4
+6 to +15	2	13.8	2	3.9	7	8.0
+5 to +5	18	50.0	33	67.3	53	60.2
+6 to -15	10	27.8	8	15.4	18	20.4
-16 or more	1	2.8	6	11.5	7	8.0
Total	36	100.0	52	100.0	88	100.0

bath. In Table 4 is presented the summary of these observations. It will be seen that approximately 60 per cent of the patients showed no significant variation in pulse rate, with a change of less than 5 beats. Approximately 11 per cent showed a pulse which was slightly higher and 28 per cent showed definite reduction of 6 or more beats per minute. The failure to find any marked variation in the rate of the pulse in this series is due to the fact that many of the patients who were studied showed a pulse rate of between 65 and 80 at the start of the cure. With a pulse rate in this normal level one could expect no striking variation. There were not a sufficient number of patients with definitely elevated pulse rates to warrant a special comparison in these cases.

The second type of analysis of the pulse was similar to that made with the blood pressures and was based on the change in the pulse rate recorded before the bath and that taken after the bath. In general, only 2 patients of the total series showed definite increase in pulse rate when the averages of the difference between the two recorded pulse rates were compared; 34 patients showed a reduction of less than 5 beats per

normal and shows relatively little reduction as a result of this course of treatment.

The review of the data presented in this paper has shown that the course of treatment is beneficial in the treatment of patients with cardiac conditions resulting from the unbalance between the two divisions of the autonomic nervous system. Other indications from the standpoint of the circulatory disorders include early myocardial weakness before the stage of decompensation is reached, convalescence from coronary thrombosis after the preliminary period of strict rest of three to six months is past, angina pectoris, and various functional disorders. It is contra-indicated in patients with severe decompensation, advanced syphilitic heart disease, severe cardiac asthma and bacterial endocarditis.

In conclusion, a definite reduction was noted in the systolic blood pressure in approximately one-half the patients in this small series who had a pressure of over 150 mm. Hg at the beginning. Reduction in the pulse rate of one-quarter of these patients also indicated improvement. As the pulse rate in the large majority of these patients was between 65 and 80 at the beginning, one could not expect any striking change in the rate. In addition, improvement, which could not be evaluated by the changes in blood pressure or pulse rate was observed clinically in the large majority of these patients.

Spa treatment, including the naturally carbonated mineral water bath, rest, diet regulation, change of scenery, and freedom from cares, is an important adjunct in the treatment of chronic cardiovascular conditions.

15 SPRING STREET

THIS AND THAT

The lid has been clamped down in Germany on patent-medicine advertising that claims to cure grave diseases and encourages self-treatment. Advertising medicines that "never fail to help cancer, diphtheria, lupus, tuberculosis, epilepsy, arteriosclerosis, etc., is barred. Lay testimonials are ruled out, and even doctors' testimonials must be solidly backed by proof.

Physicians in Toronto have agreed to attend unemployed relief patients at one-half the regular fee, of which two-thirds will be paid by the province and one-third by the city. No physician is to receive more than \$100 a month from this source. It is considered much better, from a mere financial viewpoint, to pay doctors a minor fee to treat ailments in an early stage, rather than to let them grow more serious and require long hospital treatment at public expense.

Many New York State physicians are unaware of the fact that they are entitled to the residential rate on their office telephones when their offices are located in their residences. The State Public Service Commission has ordered that the residential rate, rather than the higher business rate, shall apply on the telephone of a physician, surgeon, osteopath, chiropractor, optometrist, chiropractor, Christian Science practitioner, veterinary surgeon, nurse or physiotherapist, when the office is in the subscriber's residence. One New York City doctor, on learning his rights, secured from the company a credit covering the overcharge for the four years he had paid the business rate.

Dr. Henry C. Sherman, Mitchill Professor of Chemistry in Columbia University and internationally known for his research and discoveries in vitamins, has been chosen for the William H. Nichols Medal for 1934. This award, presented annually by the New York section of the American Chemical Society, was announced by Professor Victor K. LaMor, chairman of the jury of selection.

The medal will be presented to Professor Sherman on March 9 at a meeting of the Chemists' Club, 52 East Forty-first Street, at which Professor Lafayette B. Mendel of Yale and Dr. C. A. Browne of the United States Department of Agriculture will speak.

The lowest death rate in the history of New York City in 1933, the fourth year of the depression, is shown in the annual report submitted to Mayor O'Brien by Dr. Shirley W. Wynne, retiring Commissioner of Health. Dr. Wynne attributed the results to "practical, realistic, long-range planning."

In showing that the city's death rate had been reduced to 10.23 for each 1,000 of population in 1933 from 11.64 in 1928 when he took office, Dr. Wynne pointed out that if the 1928 death rate had prevailed there would have been 10,354 more deaths than actually occurred in 1933.

Contracts amounting to \$882,486 have been awarded for the construction of a state hospital for tuberculosis at Mount Morris.

DIRECTORSHIP OF THE SCHOOL HEALTH PROGRAM

By IRLDRICK I. PAIRY, MD.

Neuropsychiatrist, State Education Department, University of the State of New York

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 5, 1933

THE purpose of this paper is to formulate briefly what I consider a basic scaffolding in qualifications for the directorship of school health education and school health service. Reference to directorship in this paper refers only to a city, county, or large district school system, or a State Education Department. Under such a directorship, there should function in each school unit a local health supervisor who may be recruited from the ranks of school or public health nurse, physical educator or nutritionist; but this person should have had a special training in the principles of school health work.

Andrew Carnegie was once asked which of the three aspects of the steel industry was the most important: the mining of the crude material, the manufacturing process, or the selling of the product. This astute industrial magnate replied in substance: Which leg of a three-legged stool is the most important? This anecdote is related in order to throw a critical light upon the opinion expressed by certain leading educators to wit, that the director of school health should (1) be an educator; (2) an administrator; (3) he may, or may not, be a physician, but should have a thorough knowledge of health and have a sound point of view with respect to the interrelationships and functioning of the various subdivisions in such a set-up.

Let us scrutinize this tripod of qualifications of the proposed health directorship stool.

Let us assume that the person occupying this ideal stool be a "career man," one who intends to consecrate himself during his active life time to full-fledged service in health education and health service. It is important that we distinguish the "career" type of person from the "opportunist." The latter merely capitalizes health work, with full- or part-time service, as a stepping stone to some other chief ambition or work. Such a person is apt to be more concerned with the pay check, more interested in developing other interests, more eager to seek opportunities for personal, economic, or professional advancement in other fields of service. This type of person is not rare in school health set-ups and may be responsible for the frequent attitude shown by many educational administrators that the school physician must be tolerated but not necessarily cultivated.

In contrast to the sequence of qualifications suggested above, I feel that we should put first things first. The basic structure or cornerstone on which depends the soundness and usefulness of the superstructure is that of medical training of a clinical nature which

qualifies a person to engage in private practice. The main thing is to *know* something. Methodology is of secondary, though complementary, importance.

The first leg of the stool, to my mind, may be unequivocally disposed of by making mandatory a physician's training and experience in order to gain best a full-bloom working knowledge of the biological sciences, health, pathologic and therapeutic aspects of the health director's responsibility. A course in medicine comes nearer to giving this basic training than a course in any other field. Furthermore, a layman or nonmedically trained health director is qualified to evaluate and criticize in sound perspective the functioning of the physician, to point out his technical professional shortcomings, or to weave into the medical inspection service, health conservation and promotion of preventive medicine, new knowledge and techniques gleaned from laboratory research, private or hospital practice as reported in medical journals and archives. In the case of the career type of director of school health there should be no ground for cavil. But in the case of those in the opportunist category, there may be room for argument from the administrative standpoint.

The second qualification should be pedagogical training of a one-year technical course in the principles, methods, history, and philosophy of education. In order to gain a liberal, cultural and academic background and perspective, the physician aspiring to the directorship of the School Health Program should have had the training or its equivalent of that usually recognized by the bachelor's degree in Arts or Science. Such an educational premedical background has been mandatory for some years for admission to our leading medical schools.

The third prerequisite for directorship qualification is that of administrative ability. Training in school administrative principles and methods may be combined with the purely pedagogical year; in fact, such training is an integral part of the teacher's training course. But let us not blind ourselves to the real issue at stake. We are not so much interested in units of credit or diplomas, but on the quality and effectiveness of educational and administrative service. Concrete performance, and not the labels we paste on a person, should be the chief criterion of fitness for the job. Administrators, like good teachers and good clinical practitioners, are born and not made. Specific training and experience, however, are desirable and oftentimes necessary to unfold such latent natural bents and potentialities. But the main things we wish to know are: what experience and with what success is a

person able to get along with others in profitably selecting personnel, in organizing and directing their work in an efficient and happy manner, be it in administration of a playground, gymnasium, hospital service, or a regiment of soldiers.

Since the director will be held responsible for the effectiveness of health teaching and physical education, as well as school medical and nursing service, he should become thoroughly acquainted with the content and methodology of each of these phases of his work. It is particularly important that he be in close touch with the medical examiners in the schools. He must be able to evaluate their professional skill and through his own example in medical examination, ability, methods, and relationships lead the way to a superior level of functioning. A working knowledge and perspective of interrelationships of all of these aspects of the director's work is essential in order to coherently unify the diversified part—functions of school health service and health education.

Just when this year of professional educational training had best be taken may be debatable. Personally, I feel that it may be taken to good advantage during the premedical years, either as electives or by spending a year in a school of pedagogy, since medical schools are not likely to establish a chair of education in the near future. However, such an innovation would have many advantages for the training of the physician to direct school health activities. On the other hand, this year in educational professional training may well be taken after graduation from medical school, preferably after a one-year internship in an accredited general hospital. Dr. John Sundwell has suggested* that the satisfactory completion of this postgraduate training be recognized by the degree of Master of Science in Health Education.†

How are we to bring about what we conceive to be the best type of personnel functioning in school health directorship? In these days of professional competition and jealousy, it would seem that the physician functioning in such a rôle would have to win the approval and good will of educators who now hold the whip hand in the selection of personnel. This may be done best by rendering superior service to that of the nonmedically trained director.

The physician is not altogether to blame for his plight since educators by and large have made little or no effort to obtain the services of outstanding medical men or to attract or hold them by offering a salary at least commensurate with that obtained in other specialties of medicine. We cannot expect the school

superintendent to pay his health director a larger salary than he himself obtains. But the health director should at least have the rank and salary of an assistant superintendent, and in the case of a State Education Department, assistant commissioner of education. Although health education should be regarded as an interdepartmental function, yet for the purposes of organization it should be circumscribed as a separate bureau in the health set-up.

In passing, may I interject the opinion, which should go without saying, but has not in some quarters, that it is the height of organization folly to place the school physician subservient to or under the direction of a physical educator. Such a short-sighted relationship is bound to lead to dissatisfaction, inefficiency, lack of cooperation, and insubordination. In the case of the opportunist and part-time school physician he may with good discernment be placed under an assistant school superintendent; but the full-time school health director should himself have the rank of assistant superintendent.

Much could be done to bring about a more desirable hierarchy of personnel interrelationships and functionings by acquainting medical students with the professional possibilities in school health work, and in providing the essential training either during premedical and preclinical years, or after hospital internship. School physicians and health program directors already in service should obligate themselves and should be encouraged by school superintendents to improve their sphere of usefulness by taking summer courses and extension work in health teaching and health education. Health education should be regarded as a specialty of public health or preventive medicine which is a medical specialty comparable to eye, ear, nose, or throat. Medical schools cannot afford to nod their heads or blink in stolid indifference to this important development in a positive health program and thus leave the direction and control of health teaching in nonmedical hands. Machinery should be set up and put into operation whereby physicians who have the interest and aptitude to enter health service and health education as a career should have the advantage of theoretical and practical training and experience in the pedagogical aspects of health education. Teacher-training institutions should be utilized for this purpose until schools of public health and hygiene in connection with medical schools create chairs of courses in health education. Fellowships, comparable to those given to physicians electing a career in Public Health Service, should be made available to physicians who may wish to prepare for the directorship of a school health program. Educators should be sensitized to recognize the supreme importance of selecting medically trained educators to head up this important work.

Why Not More Committees On "High Costs?"

Now that the Committee on the Cost of Medical Care has gone on into the limbo of the past, we may well wonder why in the world the family's doctor bill was picked out for all the ado and to-do, and nothing done about all the other, bigger bills.

It would seem only natural, at least, that an investigation into the family doctor bill should be followed by an inquiry into the family automobile bill, usually about twice or three times as large. If the American "white-collar" class are suffering so terribly under the doctor bill, think of their agony under the automobile bill. But our statesmen at Washington are not appointing any committee to tour the land, at public expense, to probe the High Cost of Automobile Care.

Then there are other "high costs." Even the medical-cost committee put the family's tobacco bill at about the same figure as the doctor bill. So which one is to be reduced? Why, the doctor bill, of course. The logic probably is that it is natural for smoke to go up, while medicine always goes down.

Next we find that the family bill for candy, soda, ice cream, and chewing gum also figures up to about the same total as the bill of the physician who is supposed to make the system do its duty again after all the above have clogged it to a standstill. The difference is that the candy, soda and gum have to be paid

for in spot cash, while the doctor's gentle reminder is tucked away in a pigeonhole and forgotten. So what? Reduce the doctor's bill, naturally.

What about Committees on the High Cost of Silk Stockings, Underwear and Pajamas, High Cost of Movies, Vaudeville and Radios, High Cost of Hair Bleaches, Face Packs and Permanents? Worst of all is the high cost of supporting politicians at Washington and the various state capitals and city halls who make the high cost of government higher and higher every year.

These are the people who seem able to discover only one "high cost"—the cost of medical care! Let us have just one more investigation, this one to reckon how much it would cost the country to be without medical care! The "high cost" of our medical care would then stand out, clear as daylight, as the most economical expense America has today.

Ways to Reach the Public

It is distressing to see hundreds and thousands of people dosing themselves with cure-alls that cure nothing and wasting their money on quacks and charlatans, and not be able to help them. It is like standing idly on the shore of a river and watching thousands drown who might be saved. Can nothing be done to remedy this tragical situation?

Not only can something be done, but something is being done by the Bronx County Medical Society. Dr. M. O. Magid, President of the Society, told about it in his inaugural address. The members of the Bronx Society have been speaking on the radio, and giving health talks and holding health conferences in the schools, for pupils and parents, and at health centers and meetings of fraternal orders. The public has responded encouragingly and is showing an increasing demand for health conferences.

The growth of this work can be seen in the fact that in 1931 only 8 physicians gave a total number of 36 talks, while at present 75 physicians are participating and the average number of talks is 30 per month. The weekly radio talks, Dr. Magid remarks, conform with the rules of the Medical Information Bureau of the New York Academy of Medicine, and the programs include a variety of topics, though tuberculosis and diphtheria prevention are stressed. The speakers also call attention to the dangers of self-treatment with

misleadingly advertised remedies. This is all in the interest of public health and in addition, says Dr. Magid, "it is our hope that when the public learns the authentic medical facts brought to them through a persistent campaign of education, the medical profession will become the recipients of a great part of 370 million dollars spent annually on patent medicines and of the 125 million dollars spent for the services of the chiropractors, naturopaths, and cultists who ply their trade among an uninformed public."

Another idea has occurred to Dr. Magid as he sees the "Christmas Club" advertisements in the windows of the banks. "Save for Christmas," they say, save for luxuries, save for gifts for other people. That is very praiseworthy, but why not another parallel campaign urging people to "Save for Sickness?" The banks would support it, sensible people would realize its value, and it would give people the money to pay for illness when it comes. Along with the advertising of the "Save-for-Sickness" campaign, useful information could be given on health topics that could be of value. If the public could be led, in this way, to cooperate with the medical profession, Dr. Magid believes that the community health would be raised to a higher standard and the profession materially aided.

Now Is the Time for Action

It is to be hoped that every member of the Medical Society of the State of New York studied carefully the report of the Committee on Workmen's Compensation, published in full in our issue of January 15. It is the product of nearly a year's work by ten distinguished physicians, and aims to secure amendments to the present law that will protect the injured workman from the "notorious racketeer rings" that now prey upon him, and to provide adequate compensation for the attending physician.

But reforms like this do not get themselves enacted automatically, or ride through to the statute books on oiled wheels. It takes work, and more work, and then more work, and now is the time for action. The proposed amendments are the result of our best medical thought, and deserve the active support of our members, both individually and collectively.

Our lawmakers at Albany will listen with respect to any communication from the physicians in their districts, and the County Medical Societies and leaders of medical opinion

have a splendid chance here to help bring one kind of justice to the injured workers and the attending physicians, and another, rougher kind to the infamous racketeers who have been preying on the sick and the injured. Let everyone get behind this legislation and show what the physicians of the state can do when the occasion demands it.

Editor for Fifty Years

It certainly would be hard to match the record of Dr. Lewis Stephen Pilcher, who is celebrating his golden jubilee this year as editor of the *ANNALS OF SURGERY*, which he founded in 1885. Dr. Pilcher was president of the Medical Society of the State of New York in 1892 and of the Kings County Society in 1900. His journal was the first surgical periodical in the English language, and is the official organ of the American Surgical Association, the New York Surgical Society, and the Philadelphia Academy of Surgery. Dr. Pilcher also has the distinction of being the youngest student ever to be graduated from the University of Michigan, where he took his bachelor's degree at the age of 17. He is now 89.

He is a Fellow of the American Surgical Association, and was its President in 1918; Honorary Fellow of the American College of Surgeons, the Philadelphia Academy of Surgery, the College of Physicians of Philadelphia, the New York Surgical Society, and the Brooklyn Surgical Society, and one time Commander-in-Chief of the Grand Army of the Republic.

Doctors Who Don't Play Ball

The men who don't play the game, the ones who won't observe the rules, make havoc in any line of work. In medicine, it is the men who refuse to join the County Medical Society, or, if they join, do not pay their dues or attend the meetings. President Louis F. Garben of the Suffolk County Medical Society, recalled in his retiring presidential address the statement of President Roosevelt that a small minority could upset all the efforts of the NRA if not whipped into line. If 10 per cent resort to unfair or sharp practices, the work of the 90 per cent will fail. In the same way, said Dr. Garben, if 10 per cent of the doctors in any county refuse to work with

the County Medical Society, "these non-members can by unethical conduct and practices give the public at large a poor opinion of the entire profession in the county."

The cure for this situation, as he sees it, is to follow the example of Denmark, where membership in the county society is practically 100 per cent, and where the county societies can determine whether a given doctor is, or is not, allowed to practice. Expulsion from his medical society there is tantamount to revocation of his license to practice medicine. Dr. Garben would amend the Medical Practice Act here to give the county medical societies the same power. Then the medical wild-catters, if we may borrow the term from the oil industry, would be brought into line, to the benefit of the profession and the public.

These are days of sweeping changes, and our lawmakers seem ready to make advances such as they would never have made in previous years. Here is a suggestion for our legislative committees to consider.

Mother's Day 1934

Mother's Day—May 13th—is to be observed by women's clubs, men's clubs, medical societies, chambers of commerce; and other professional and civic groups who will join in community efforts throughout the nation to "make motherhood safe for mothers." The Maternity Center Association of New York has taken a leading part in this noteworthy movement. We are glad to give space to the following announcement by the president of the organization, Mrs. Shepard Krech:

"In previous Mother's Day campaigns, the effort was to arouse the public to the fact that two-thirds of the maternity deaths in the United States are preventable; that 10,000 of the 16,000 women who annually die in childbirth could be saved. The next move, which is to be taken this year, is to do something quite specific and definite about it, with groups working in every community.

"Specific changes cannot be made to improve conditions until people study their own local maternity facilities, and determine just what is needed. The phases requiring attention may differ widely in various communities. The Maternity Center Association has undertaken to supply blank appraisal forms which will aid local groups of interested persons, medical and lay, in conducting investigations into the adequacy of what their own town or county is doing for mothers. Such questions as these are to be answered: 'Number of maternity beds?' 'Total number of births in the last year?' 'Number of deaths in the last year?' 'Is organized prenatal nursing service provided?' 'Is your hospital approved by the American College of Surgeons?'

"A great deal of sentiment has developed surrounding Mother's Day during the time that it

has been observed in this country. In the last few years there has been a successful effort to direct this fine feeling toward the important subject of saving mothers from unnecessary death. But emotion alone is not enough. We must have facts, pertinent facts, local facts, so that groups in every community may work with their own physicians, health officers, nursing associations, and hospital authorities to alter those factors in the situation which are a barrier to safe motherhood.

"Only by an appraisal of maternity facilities in every community, and a study of their quality, can the great step forward be taken. These blanks are available free. Prizes are to be awarded to those groups which have the highest rating for making a thorough-going survey and presenting a plan for improvement based upon that survey. Programs for club meetings are also available without charge, as well as publicity material for local Mother's Day campaigns designed to direct the sentiments surrounding this occasion into channels that will be productive of results in terms of human lives saved."

The address of the Maternity Center Association is 1 East 57th Street, New York City.

Disagreement On Sterilization

An intelligent amount of sensible skepticism should be applied to the newspaper reports of wholesale sterilization in Germany. The first dispatches had it that 400,000 men and women were to be sterilized as physical and mental defectives who might transmit their weaknesses to their offspring to the injury of the German nation. This huge number has been whittled away in succeeding dispatches until it is clear that we must wait for more reliable information before we know what will happen.

We do not have to look to any foreign country, however, to see this plan in practice. It is now legal in 27 states of the Union, and has been sanctioned by the U. S. Supreme Court in the case of *Buck vs. Bell*. The Court's decision is cited by Dr. J. H. Landman in his informing work entitled "Human Sterilization" (Macmillan). This case had to do with the sterilization of Carrie Buck, a feeble-minded woman in the Virginia State Colony for Epileptics and Feeble-minded, of which J. H. Bell was superintendent. Carrie Buck was the daughter of a feeble-minded mother, an inmate of the same institution, and the mother of an illegitimate feeble-minded child. The decision of the Supreme Court was written by Justice Holmes. He said, in part: "It is better for the world, if, instead of waiting to execute degenerate offspring for crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind. . . . Three generations of imbeciles are enough."

All cases are not so simple, however. History has enough examples to confirm the poet's line, "Great genius is to madness near allied." In one decade Darius Green, with his flying machine, is a fool or a lunatic. In the next, Wilbur and Orville Wright are geniuses. In one decade a man is a criminal because he breaks a law that is repealed in the next. The law is repealed, and he may be released, but if he has been sterilized, his rights cannot be restored to him. In Dr. Landman's opinion criminals should not be subjected to compulsory sterilization, for crime is "nothing but the evidence of a maladjustment between the individual and society" and "criminality itself is not inherited." If the criminal has hereditary feeble-mindedness or mental disease, then he should be sterilized to halt the evil heritage, but not for his criminality, for Dr. Landman holds that to be an acquired trait. "So, too," he adds, "the blind, the deaf, the deformed, the paupers, the inebriate, the lepers, the syphilitic, the drug fiends, and others are the socially inadequate classes in our society that have primarily acquired their deficiencies. They do not transmit their shortcomings, as such, to their offspring. They ought not to be sterilized. They need vocational, mental, or medicinal therapy. Where, however, in individual cases of these classes, the insufficiency was inherited and will be transmitted—then the potential progenitors of these weaknesses

should be sterilized. The human sterilization program provides for the sterilization of individuals—not classes—whether they be social, economic, political, or religious classes."

Segregation, rather than sterilization, is the best remedy, Dr. Landman believes, for it would do everything that sterilization does in preventing propagation of these social units and would "remove the many dangers to society which would arise from their freedom."

On the other hand, many of the best physicians in the States having sterilization endorse it strongly, and it is reported gaining in favor in Great Britain and other European countries. It is a vital subject and should have the guidance of our best medical minds and not be left to the decision of political office holders and of ignorant, if well-meaning, social theorists. The British governmental committee which has been considering this matter unanimously recommends voluntary sterilization to remove the dead weight of social inefficiency and individual misery entailed by the existence of more than 300,000 mental defectives. Compulsory sterilization is unanimously rejected. The mass of defectives is being steadily recruited, the committee declares, and "without some measure of sterilization these unhappy people will continue to bring into the world unwanted children, many of whom will be doomed from birth to misery."

The Thomas W. Salmon Memorial

The Committee of the New York Academy of Medicine in charge has set forth in a report by Dr. C. C. Burlingame to the Annual Meeting on January 4th, 1934, its decisions and actions in administering the fund.

In pursuit of the purpose of the Memorial to aid "the better treatment and prevention of mental disorders and promotion of mental health," the Committee has chosen Dr. C. Macfie Campbell, Professor of Psychiatry at Harvard University, to deliver the Memorial Lectures on April 13th, 20th, and 27th, 1934.

Subsidies have been granted to the following research projects:

Miss Muriel T. Bashlow, Judge Baker Foundation, for studies on psychometric results of clinical psychotherapy in cases of emotional blocking among juveniles.

Dr. Clarence O. Cheney, New York Psychiatric Institute, for endocrinological studies in psychiatric patients.

Dr. Franklin G. Ebaugh, Colorado Psychopathic Hospital, Denver, for studies on treatment of epilepsy with emmenin (the name applied by Pro-

fessor Collip of McGill University to a hormone study of therapeutic approaches to enuresis.

Dr. Norman Fenton, Bureau of Juvenile Research, California, for a study on the mental and social traits of 400 boys in a State Correctional School and the relationship of these traits to later behavior on placement.

Dr. John Levy, New York, for an experimental study of therapeutic approaches to enuresis.

Dr. Jacob Kasanin, Clinical Director, State Hospital for Mental Diseases, Howard, Rhode Island, for the purchase of an oscillogram for investigation of the peripheral circulation in schizophrenia.

Dr. James L. McCartney, Director, Classification Clinic at Elmira, New York, for a classification of prisoners.

Dr. Lloyd H. Ziegler, Professor of Psychiatry and Neurology at Albany Medical School, for a study of psychopathic effects and their relation to the surface temperature of the body.

The Editorial Board of the Archives of Neurology and Psychiatry, for the reprinting and distribution of certain articles dealing with the training of the neurologist and psychiatrist.

CORRESPONDENCE

Anonymous letters will not be noticed. All communications must carry full name and address of the writer, but these are omitted on request.

Thanks!

The Editors of the JOURNAL have received a great number of suggestions and criticisms, and they wish to thank their subscribers for the interest shown in the new form of the JOURNAL. Because of the limitations in space, it is possible to publish only a few of these letters here.

In response to a number of suggestions the Editors have decided to use a larger type size beginning with the issue of February 15th.

In the meantime, any further suggestions for the improvement of the JOURNAL will be gratefully welcomed.

A New Crusade Suggested

To the Editors:

My compliments on the JOURNAL in its new format. I think that it is ever so much more attractive than it was in the old form. I read with particular interest the note from a medical writer in Kansas who expressed the hope that "the day may come, and soon, we hope, when one can sit by his radio and get a genuine and continuous thrill of Wagnerian opera without being interrupted by a radio announcer who tells the audience of the air what it should take to make its bowels move."

Of course, the proprietary medicine people have taken advantage of the new mode of publicity, quite as they did of the newspapers and other means of publicity years ago. I recall that one of the first special articles that I wrote for a medical journal when an assistant editor some thirty-five years ago, was with regard to the abuses of medical advertising. The case seemed hopeless then, and yet after a while there came a time when reputable newspapers refused to accept medical advertising.

The medical profession made itself felt in that crusade to excellent effect. Why shouldn't we do it again, and why shouldn't the new NEW YORK STATE JOURNAL OF MEDICINE be the pioneer in this new crusade?

JAS. J. WALSH,
110 W. 76th St.,
New York, N. Y.

To the Editors:

Congratulations on the new format of the STATE JOURNAL: it is easy to handle, and easy

to read, and its editorials are worthy of emulation by many other medical publications.

Doctor Heyd's editorial on the present hospital and dispensary situation is filled with common sense, and should be read by every Medical Board and Board of Trustees of our hospitals and dispensaries.

The book reviews are splendid, even if they are all commendatory: may I suggest than an item or two, or a short article on the lighter side of medical work would be acceptable to many of us. Congratulations and hope you can keep up to the standard of Volume 34, Number 1.

DR. JOSEPH BAUM.

Asks Advice on a Hard Problem

To the Editors:

A newspaper recently stated that a Committee had been appointed by Governor of the State to investigate the Workmen's Compensation Law and make suggestions for its revision and improvement. Lately, the writer had had two annoying experiences. He feels that the citation of the facts in his case may guide the members of the Medical Society of the State of New York. He asks that this entire communication be published in an early issue of the JOURNAL.

The Great American Indemnity Company, through one of its local

representatives phoned and asked me to examine a workman carried by their Company. The report was rendered and a bill sent. The bill was not paid. A hearing was held before one of the Compensation Commission referees and the claim was disallowed because it was said to be a contract between the insurance company and the writer. The referee very kindly stated that the writer's recourse was to common law.

The second case was with the Indemnity Company of North America. An employee was sent by his employer with a letter directing me to care for him. Treatment was given and the recovery was complete. The carrier refused to pay the bill. The referee stated that because the employer had asked for my services it was a contract between employer and physician and not between the insurance carrier and the physician.

The referee was asked how the physician might protect himself under these conditions;

(Turn to page 118)

SOCIETY NEWS

Committee on Public Relations

While no less than eight important subjects are engaging the attention of the Committee, it is desired that the County Societies and the membership at large focus their thought on one particular matter at this time; that is, the worth of Surveys of Efficiency of Public Health Organization within County limits.

The Jefferson County Medical Society requested and secured such a "survey" for Jefferson County through the medium of the State Department of Health. That survey revealed enough defective conditions to bring the newspapers into the field. The press advocated a publicity campaign to remedy these defects.

This Committee believes that here is an opportunity for County Societies to assume leadership in improving the supply of health services to the population of their Counties. It is also of the opinion that the County Societies would do well to call to their aid help from any source that might seem desirable.

Further study of this subject is being undertaken by a sub-committee consisting of Drs. W. H. Ross, Thomas H. Cunningham and George M. Fisher. In the meantime it is suggested that County Societies consider the advisability of making surveys along this line.

WILLIAM H. ROSS, *Secretary.*

Errors That Hamper The Education of Deaf Children

BY ANNETTA W. PECK

Executive Secretary, the New York League for the Hard of Hearing, Inc.

EDITOR'S NOTE: "Hearing Problems Engage Cooperating Committees." Confusion and waste motion, it seems, are hampering the smooth working of the state machinery that operates to educate the children who are deaf or hard of hearing. These misunderstandings can be eliminated by a frank interchange of information and advice, and a campaign of enlightenment for this purpose is about to be launched by three cooperating committees. Literature will be sent to every physician in the State. A careful perusal of it, and preservation for future reference, will prevent the errors that now interfere with the work for these unfortunates. This article by Miss Peck tells what some of the errors are.

Information regarding the widely prevalent hearing problem will soon be placed in the hands of every physician in the State of New York through joint action of the New York State Medical Society's Committee on Public Relations and Public Health, their sub-Committee on the Deaf and the Hard of Hearing and the State Department of Education. This information will be released in compact printed form and will include a statement of facts and also recommendations for procedure.

The three cooperating committees named are convinced that family doctors and otologists are not, generally speaking, sufficiently well acquainted with the work now going on in the field of conservation of hearing, nor with conditions in schools for the deaf, of which there are three day and seven residential schools in the State. With regard to these special schools it would appear desirable to review the present law covering admittance on some kind of medical report from persons who may, or may not, be qualified to make such reports. It is also a common practice to admit children to these schools without any kind of otological examination. This practice could be checked by acquainting every family doctor and every otologist with the importance of reporting every case examined by them to the State Department of Education and by providing the State Department with a list of otologists who could be called upon to make examinations in their community for a definitely stipulated fee.

Another important point is that neither public welfare laws nor educational laws include or provide otological care of the children in schools for the deaf. Most schools, however, make such provision of their own initiative and through their understanding of the otological problems involved.

The second objective, which lies within the scope of conservation of hearing, deals with the medical care of children whose hearing is threatened (potential impairment) and those whose hearing is already permanently impaired. Both classes are large. From 4 to 10 per cent of our school children show some impairment of hearing. These figures are based on the findings of surveys made in different sections of the country as well as by the Bureau of Medical Inspection of the New York State Department of Education, and the extensive surveys in New York City and adjacent parts of the State by The New York League for the Hard of Hearing, Inc. Children in these two classes are considered to be

in special need of otological care, the first (potential), in order that their hearing may be conserved, and the second, in order that their hearing may be improved under treatment if possible, and in the case of permanent impairment, that further losses may be avoided, attention being directed to general health and nutrition as well as aural hygiene.

It should be noted that these latter children are what is called *hard of hearing*, that is, they have lost a part or even all of their hearing *after having been with normal hearing* and having *normal speech* naturally acquired and well established. Deaf children, on the other hand, are classified as those who were either born without hearing, or who lost their hearing *before speech was established*. One unfortunate consequence of the present procedure of admitting children to schools for the deaf on a report by unqualified persons is that 30 per cent of the children in such schools are not deaf at all, but *hard of hearing*. Confusion undoubtedly exists in the popular mind as to the difference between the deaf child and the hard-of-hearing child, so that many children with slight hearing impairments are unnecessarily receiving from the State the comparatively expensive education which is required to prepare deaf children for adult life. The clarification of hearing problems as planned by the committees named is a necessary foundation for constructive dealing with hearing problems and in itself will be a definite service to the physicians, educators, social workers, parents, and other taxpayers of the State of New York.

Committee on Legislation

Bulletin No. 2, Jan. 19, 1934

Since writing our last bulletin the following bills have been introduced:

Senate Int. No. 151—Byrne, (Assembly Int. No. 166—Cahill), adds new section to the Penal Law authorizing a society for prevention of cruelty to animals to seize animals abandoned or found wandering at large and on certificate of veterinary surgeon, destroy any diseased or disabled animal, and deliver any unredeemed animal to person other than owner. Referred to the Codes Committee.

We need have no particular interest in this bill, we are reporting it largely so that you will be familiar with it and not confuse it with an antivivisection bill which may later appear. This is definitely not an antivivisection bill.

Senate Int. No. 155—Berg (Assembly Int. No. 128—Condon), to amend the Education Law to permit restoration by Regents of license to practice medicine to a person paid

done after conviction of felony for misconduct in his professional capacity. Referred to the Education Committee.

You will recall that Senator Berg carried this bill last year. We effectively opposed its advancement on the ground that "misconduct," which the law provides shall be a factor in deciding whether a physician's license shall be restored or not, is determined by the Medical Society. We are the guardians of our own Code of Ethics and the law so regards us, but if this amendment were to be enacted into law the deletion would remove from us the decision as to conduct and leave it with the Board of Regents.

Assembly Int. No. 77—Theodore, adds new section to the Education Law, prohibiting certain acts in practice of medicine as selling articles or contents bearing mark or symbol pertaining to advertising or medical care or to any inducement relating thereto or employment by any person or group, other than licensed physicians, of any person other than a physician for the practice of medicine. Referred to the Education Committee.

Assembly Int. No. 81—Theodore, to amend the Civil Practice Act, giving preference to personal injury actions where plaintiff presents proof that he has not sufficient means to support himself or dependents and is physically unable to earn reasonable wages. Referred to the Codes Committee.

Assembly Int. No. 100—Hamerman; Assembly Int. No. 172—Flynn, Assembly Int. No. 178—O'Mara—three garnishee bills. Referred to the Judiciary Committee. The latter two are identical and are concurrent with Senate bill Int. No. 31, by Mr. Cilano.

Assembly Int. No. 108—Stewart, amends the General Municipal Law for payment of medical expenses to injured volunteer firemen or representatives in case of death and also to firemen temporarily incapacitated or disabled as a result of certain injuries. Referred to the Judiciary Committee.

Assembly Int. No. 215—F. M. Smith, to amend the Agriculture and Markets Law by requiring the licensing of persons who sample, handle or prepare milk or cream in making milkfat tests. Referred to the Agriculture Committee.

The law at present requires that persons making milk-fat tests must be licensed. This amendment also includes for licensure any who sample, handle or prepare milk for the tests.

Assembly Int. No. 221—Thompson, to amend the Agriculture and Markets Law, making it unlawful for a wholesaler, retailer, commission merchant or jobber to expose for sale

food stuffs in open containers placed outside a building or entry way unless they are so placed that no part shall be within 20 inches of level of platform or walk on which public is invited to travel. Referred to the Agriculture Committee.

Assembly Int. No. 224—Whitney, adds new section to the Agriculture and Markets Law, repeals 6-a, 6-b, Health Law, transferring to Department of Agriculture and Markets all powers and duties of Health Department for sanitary control and inspection of milk and cream. Referred to the Agriculture Committee.

The personnel of the four Assembly committees with which we have most of our dealings follows:

CODES

Robinson of Tompkins	Parsons of Onondaga
Sheldon of Lewis	Haskell of Cortland
Dickey of Erie	Ross of New York
O'Mara of Monroe	Alterman of New York
Heck of Schenectady	Farrell of Queens
Brunstrom of Chatauqua	Moran of Kings
Suitor of Niagara	Hawkins of Kings
	Schwartz of New York

PUBLIC EDUCATION

Ives of Chenango	Murphy of New York
Lewis of Oswego	Fite of Dutchess
Averill of Wayne	Lewis of Richmond
Taylor of Orange	Bauer of Kings
Corwin of Schuyler	Gillen of Kings
Hamilton of Rockland	Farbstein of New York
Milmoe of Madison	

PUBLIC HEALTH

Lewis of Oswego	Bauer of Kings
Pollard of Seneca	Doyle of Kings
Bush of Delaware	Kantowski of Erie
Ives of Chenango	Bernstein of New York
Burgdorf of Cayuga	Goldstein of Kings
Vincent of Broome	Lavery of Westchester
Murphy of New York	

LABOR AND INDUSTRIES

Messer of Steuben	Berley of Kings
Miller of Tioga	Morris of Saratoga
Goodrich of Allegheny	Breitenback of Kings
Thompson of Orleans	Canney of Erie
Washburn of Columbia	Breen of Rensselaer
Rapp of Genesee	Kelly of Monroe
Corwin of Schuyler	

Our annual request that the committees of the County Societies develop a close liaison with their legislators can not be too forcibly expressed this year. With many new chairmen and with one-third of the personnel in the Assembly new, it is to be expected that persons and organizations that have had difficulty in securing legislation opposed by the Medical Society, will endeavor to do so this year, hoping that their arguments will be more effective with the new personnel.

Rather authentic information has reached us that the chiropractors have prepared and will have introduced a bill to provide for their licensure. Without doubt they will ask for an individual examining board and for exemption from the high requirements that they set, for a certain number of those who are illegally practicing in the state at present. Don't wait for the appearance of the bill before you begin discussing the matter with your legisla-

tors. Acquaint them with the fact that we have great pride in the educational standards developed by the Department of Education for the protection of the public against ignorant practitioners of medicine or preventive medicine, and secure from them when possible a pledge to maintain these high standards, for after all our opposition to chiropractic or any other cult lies not in the method or system so much as it does in the effort the practitioners of those schemes always make to lower our educational standards. When the bill appears we shall send you a careful analysis of it and probably will suggest at the time that you give as much publicity to our position in the matter as you find possible and convenient.

Have you read the report of the Governor's special committee to investigate compensation practices in the state? If so, what are your suggestions with regard to the preparation of amendments to the law? The committee that prepared the report is anxiously awaiting comments from the County Societies.

Civil Works Administration

The following letter has been received from the Legislative Bureau of our Society:

Dear Doctor:

Since issuing our last bulletin with regard to medical service under the Civil Works Administration, we have learned that the United States Employees' Compensation Commission will take over the provision of medical care to employees under the CWA. We wrote to the Commission in Washington asking for authoritative information upon the matter and on January 8th received the following reply:

"The Commission is in receipt of your letter concerning the appointment of physicians for the care of injured employees of the Civil Works Administration in your vicinity.

"As the work being undertaken by the Civil Works Administration is presumably of a temporary nature, it is not intended to increase materially the number of designated physicians. On the other hand, in view of the widespread character of this work, the Commission is extending authority to local administrators to refer cases to private practitioners as well as physicians previously designated. Therefore, bills for services rendered injured employees of the Civil Works Administration by private physicians may be forwarded to the Commission, through the office of the local administrator, and will be given careful consideration."

And on January 11th we had the following communication from the Civil Works Administrator of the state:

"From: United States Employees' Compensation Commission

To: State Civil Works Administrators

Re: The Selection of Private Physicians for Compensation Work

"Please instruct your local administrations to consult the officers of their County or District Medical Societies at once to enlist the societies' cooperation as follows:

"1. Ask them to share with you the responsibility of preparing a list of the local physicians authorized to provide treatment to supplement Federal Government medical facilities

when these are not available or are inadequate. This list should include physicians in the locality (whether members of the local medical society or not) who are well qualified by training and experience to render compensation service, who are licensed to practice medicine in the state, and who desire to participate in this service under the regulations of the United States Employees' Compensation Commission. These regulations provide for fees not in excess of those charged by physicians generally to patients in the same income class as the injured person.

"2. Have them indicate on this list physicians who, by training and experience, are especially qualified to handle unusual and special types of cases.

"3. Request that they work out with you a proper plan, mutually satisfactory for distributing the compensation work among the physicians on the list in as equitable a manner as possible. Any plan should provide for the immediate treatment of emergency cases, and for treatment by physicians well qualified to handle the particular type of case.

"A cumulative record should be kept which will show the number of cases which have been assigned to each physician on the list."

It is suggested that every County Society prepare a list of the physicians who are ready and willing to treat employees who may need medical care. This list should be presented to the county CWA director. If he has occasion to refer patients, it is the intention of the Commission that he should allow the employee to select his family physician if he is on the list; if not, then to select some physician from the list.

Each sizable project will regularly have a first-aid director who will provide to the workers on the job first-aid education and facilities. If an accident occurs, he will take such measures as the men in the front-line trenches did and send the case home or to a hospital, where a physician from the certified list will be called to take care of it.

Physicians should immediately secure proper

information blanks from the CWA director. The compensation bureau is very exacting in its demands for information. In every county there are already some physicians who are doing federal compensation work. These men can remain on the list if they choose, but whether they do or not the County Society should prepare a list as stated above. There is no limitation to the size of the list, but the Society is expected to make itself more or less responsible for the serious intention and character of work of those whom it recommends. The Federal Government is willing to pay the fees that a physician would regularly get for services of the same character in private practice and, therefore, physicians should exercise care in preparing their bills.

This matter was submitted to the Executive Committee of the State Society at its monthly meeting on Thursday, January 11th. The Committee at the time passed a resolution that since experience has shown that psychologically and economically the best treatment of the sick is afforded under the case method, welfare workers and other public officials with the responsibility of providing medical care should be urged to secure it in this manner rather than by the employment of physicians on salary.

JOSEPH S. LAWRENCE,
Executive Officer.

It is reported from Buffalo that actual authorization for the employment of twenty-six physicians has been announced and that the County Society seeks provision for four more. These men are to work two hours a day for six days in the week in the Dispensary of the City Hospital or to visit in their homes indigent dispensary patients who are unable to come to the Dispensary. The compensation is to be \$1.75 an hour. This rate was arrived at after consideration of the statement by the Committee on the Costs of Medical Care that the average net annual income of a physician is \$3,500.

Dr. John Van Duyn Civil War Surgeon and World War Surgeon

To have practiced surgery for nearly 60 years is in itself an unusual feat. To have been an active surgeon in the Civil War, and again an active surgeon fifty-odd years later in the World War is an extraordinary record.

Dr. John Van Duyn of Syracuse, who died January 15th, 1934, at the age of 90, accomplished this extraordinary spread of war experience in surgery. During the intervening years he practiced surgery in Syracuse in such successful fashion that he had long been known affectionately as the "Grand Old Man," or simply as "Dr. John." He continued his active practice to the age of 85.

He was the oldest living alumnus of Princeton University, where he graduated in 1862. He joined the faculty of the College of Medicine at Syracuse when it was founded, and taught surgery and historical medicine there for more than half a century.

His experiences in the Civil War inspired a hatred of warfare that colored all his later life and he declared on his return from the World War that the whole business, despite all efforts at improvement, remained just as destructive, painful and cruel as it was nearly 60 years earlier.

The new Physical Therapy Department of the New York Polyclinic Medical School and Hospital was opened on Monday, December 11th, 1933. Many prominent physicians and

surgeons, as well as other guests were present. This department is located in the new clinic building of the Polyclinic Hospital, and is supervised by Doctor Richard Kovacs.

COUNTY NEWS

Albany

Opposition to Berg bill was recorded at the January 24th meeting. This bill gives the State Department of Education full power to restore the license to practice medicine and surgery to those individuals who through conviction of felony or misconduct in professional capacity have lost their licenses.

Use of Chancellors' Hall for Undesirable Speakers on Medical Matters—The Society protested to the Board of Regents against the use of the Hall by any person or persons for the purpose of addressing public gatherings on medical matters unless they are recognized authorities capable of advising and having the full confidence of the profession. This protest arose from recent use of the Hall by the head of a Sanitarium which had been severely condemned last spring in the columns of the JOURNAL OF THE MEDICAL ASSOCIATION.

Dutchess Putnam

Society Entertains Mayor Spratt of Poughkeepsie.—George V. L. Spratt, newly elected Mayor, was entertained at dinner on January 13th. Judge Spratt had for many years been the legal counsel of the Society.

Erie County

Elsewhere it has been noted that the physicians to serve in the Buffalo City Hospital Dispensary will receive \$1.75 an hour. The question has been raised whether this does not suggest State Medicine since the payment comes from the Government Agency, though the emergency feature of the situation is well recognized.

Kings County

Combined Scientific Study by Dentists and Physicians.—Although not a formal "combined" meeting, the Kings County Dental Society has arranged for a Symposium which has the same effect. Dr. Joseph Colt Bloodgood, Johns Hopkins University, will present the medical aspects of "Oral Manifestations of General Systemic Diseases and Their Sequels," and Dr. Lester R. Cahn will give the dental viewpoint. The meeting will occur at 3:00 P. M. on February 15th, 1934, at the Brooklyn Cancer Institute, 109 Cumberland Street, Brooklyn.

Nassau

Should a County Society Assume the Responsibility of Making Nominations for Local Commissionerships under the Alcoholic Beverage Control Law? The Nassau County takes the negative in the following resolution which was unanimously adopted on November 21st, 1933:

WHEREAS, the Constitution of the Medical Society of the State of New York clearly sets forth the purpose of the Society, "to secure enforcement of just medical laws, to enlighten

and direct public opinion in regard to the great problems of medicine" and *WHEREAS*, the Alcoholic Beverage Control Law, delegating to respective County Medical Societies the responsibility of nominations of local commissioners, assigns to the Society an action that is not concerned with a great medical problem and is outside the proper field of activity of the Society, and

WHEREAS, with the probable repeal of the Eighteenth Amendment, the County Societies will have their duties extended in this field, and

WHEREAS, the further discharge of such duties will tend to jeopardize the honorable professional standing which the Medical Society of the County of Nassau has sustained in its other activities, it is therefore

RESOLVED, that the Medical Society of the County of Nassau take a definite stand in regard to its activities in this politico-social problem, and it is further

RESOLVED, that this Society go on record as being opposed to further functioning in this field of activity, and it is further

RESOLVED, that a report of this action be transmitted to the Medical Society of the State of New York both by our delegates at the next Annual Meeting and in any other way that the Comitia Minora sees fit.

New York

A Step Toward Solution of the Dispensary Problem.—During the year just passed the County Society found means to secure satisfactory and effective conferences between its Economics Committee and the Hospital of the County which has established sound and equitable principles for conducting Dispensaries that are satisfactory to both groups. These principles should go far to solve the general problem of the Dispensary and the private physician.

Excerpts from the Annual Report of the County Economics Committee follow:

"The Hospital group known as the Out Patient Committee of the Hospital Conference, the Chairman of which is Dr. Frederick MacCurdy, represents 65% of the total out-patient department admissions in New York County, fourteen hospitals all of which are members of the United Hospital Fund.

The matters agreed upon in mutual conference are as follows:

1. The function of the Out-patient Department was adequately defined: Namely—

A. Adequate medical care for all persons who cannot afford to pay for services of a private physician.

B. Cooperation with doctors and provision for teaching facilities for graduate and undergraduate physicians, nurses, and dietitians.

C. To provide investigation of the costs for the cure of disease.

2. The Economic standard of the financial

eligibility to be applied to patients for Out-patient department care.

(This standard was the standard presented by the Special Committee on Hospitals and Dispensaries of the Medical Society of the County of New York, a copy of which is enclosed.)

3. A common standard for reception and classification of applicants. A definite form for registrars and a school for registrars so that they may learn to adequately fill out this form.

Where necessary or where fraud is suspected, the Hospital applicant is to sign a proper affidavit.

4. A common denominator, to be worked out, for Out-patient admission and special charges, is necessary because of the wide variation in the fields of individual institutions. It was agreed that the basic principle to be observed in fixing fees for the clinic, both admission and special, was to establish rates that were non-competitive with the practicing doctor.

5. Central registration, it was agreed, was impractical and was postponed for further study.

6. *Pay of Physicians.*—It was recommended that the Conference go on record as favoring some method of paying the physician working in the Out-patient department, if and when means to finance such an expense can be found.

7. *Hospitals Showing Profit.*—It was recommended by the Committee that the Hospital Conference go on record as recommending that no Out-patient Department should be operated on a profit. Furthermore, that some standard of bookkeeping, such as advocated by the United Hospital Fund be employed so that a standard procedure might be followed in all Hospitals and therefore similar bases of cost figures be developed.

8. *Professional Standards.*—It was agreed upon that professional standards should be developed and set up for minimum standards of Out-patients care and that Hospitals be graded according to the observance of such a standard. This should include limitations of intake, adequate records, sufficient clerical and nursing help.

All of these general principles were accepted in principle by the Comitia Minora of the Medical Society of the County of New York and by the full Committee of the Out-patient Department Committee of the Conference of Hospitals.

The details of each principle are at present being worked out in small Committees and will be the subject of the report for the year 1934.

The Committee on Economics introduced to the Comitia the recommendation that physicians working in Out-patient Departments of City Hospitals should be paid. The Comitia approved the recommendation, and the Committee on Economics is investigating the number of physicians, the basis of payment, and

the amount of additional expense it will be to the City of New York for payment of these physicians.

At an opportuna time, a bill will be introduced before the Board of Estimate, to include this sum in their budget for the coming year.

Eligibility for Admission to Dispensaries:

It was agreed that an unmarried applicant without dependents earning \$900 or less per year should be admitted for dispensary care. The following minimum schedule was considered a fair one to guide admitting officers in the matter of patient's financial ability to pay for private service.

Single individual	Annual income	\$900
Family of 2		1400
" " 3		1650
" " 4		1900
" " 5		2150

(Add \$250 for each additional dependent)

The total family income is to be considered where parents and children are working.

Dr. Charles H. Nammack has been appointed Director of the Fourth Medical Division of Bellevue Hospital, succeeding Dr. Alexander Lambert. Dr. Herman O. Mosenthal has been appointed visiting physician on the same division.

Ontario

Payment for Welfare Work by the Case Method.—For two years this County Society has endeavored to do the welfare work of the County within the budget allowed by the board of supervisors. The first year that budget was only \$3000. An agreement was reached with the public health committee of the board of supervisors that physicians should do all of the welfare work that was requested by the various welfare commissioners and record at the end of each month the work they did. Records were kept and at the end of the year the \$3000 was divided among the physicians pro rata according to the work done. It resulted in the physicians being paid for their work at the rate of 16 cents on the dollar. The next year, with great difficulty, the physicians persuaded the board of supervisors to increase its appropriation, but the increase was only \$2000 and that was hardly sufficient to take up the increase in demands that resulted. Naturally, the physicians have been dissatisfied with the plan and at their annual meeting the other day they voted to discontinue that arrangement and ask the welfare commissioner to compensate them for their services by the case method, which is proving much more satisfactory in other countries.

Seneca

Request for a Milk Commission.—The secretary of the Seneca County Society and the president of the Seneca Falls Hospital have asked the County Society to appoint a milk commission to investigate the quality of milk supplied to Seneca Falls. Complaints have been received that impure milk is being distributed in some instances in the village. A resolution adopted by the hospital staff calls

upon Governor Lehman to include in the 1934 budget a sum sufficient to cover the tuberculin testing of all herds now untested and to provide for the annual retesting of accredited herds. The resolution in part reads: "At the present time there is no regular way open for producers to sell their products as certified milk and the County Medical Society offers the only way for a producer to become qualified for the production of certified milk in the State by appointing a county milk commission."

Queens

Minimum Tuberculosis Library for Physicians—The Bulletin for December, 1933, indicates approval by the Society of the selection by the Queensboro Tuberculosis and Health Association of a Minimum List of books on Tuberculosis that a physician should have. The list follows:

Intestinal Tuberculosis, by Lawrason Brown, M.D. and Homer L. Sampson.
Pulmonary Tuberculosis, by Morris Fishberg, M.D.
The Natural Process in Healing Pulmonary Tuberculosis, by Marc Jacquerod, M.D.
Light Therapy, by Frank H. Krusen, M.D.
Procedure in the Examination of the Lungs, by Arthur F. Kraetzer, M.D.
Modern Aspects of the Diagnosis, Classification and Treatment of Tuberculosis, by J. A. Myers, M.D.
Tuberculosis Among Children, by J. A. Myers, M.D.
The Childhood Type of Tuberculosis, by E. L. Opie, M.D., J. D. Aronson, M.D., F. M. McPhedran, M.D., and H. D. Chadwick, M.D.
Surgery of the Chest, by George F. Straub, M.D.
Laboratory Diagnosis and Experimental Methods in Tuberculosis, by Henry S. Willis, M.D.

Correspondence

(Continued from page 111)

however, the answer was not sufficiently clear to quote him.

Will you please, in the columns of your JOURNAL, explain in detail how a physician may avoid such evident gross imposition?

M. D., ALBANY.

Thanks for the Correction

To the Editors:

In your salutatory you call for criticisms on the new JOURNAL. I will remind you that new officers for County Societies take their office the first of January.

You have published in your list of officers of County Societies, the name of the President of the Washington County Medical Society for last year. Our President for this year is Dr. Roy E. Borrowman. Secretary and Treasurer are correct.

I refer you to the heading of this letter for all of the officers of the Society.

S. J. BANKER, *Secretary*
The Medical Society of the
County of Washington

To the Editors:

Please allow me to congratulate you on the marked improvement in the appearance of the NEW YORK STATE JOURNAL OF MEDICINE. . . .

On page thirty of the new edition, the 1933 officers of the Schenectady County Medical Society are listed. If you have not already done so, will you change this to read: J. J. York, President; E. K. Cravener, Secretary, and F. Mulcare, Treasurer. These physicians are residents in Schenectady.

EDWARD K. CRAVENER, M.D., F.A.C.S.

Scatter the Seed—the Wider the Better

To the Editors:

Congratulations on your new JOURNAL

"dress." I have been enjoying a pleasant evening leafing your issue of January first . . . I am interested in the article on pages 23, 24, 25 "Unified Action," "Food and Drugs Act," "Medical Sensationalism in the Press," and especially in the article "Doctors Say." . . . I should like to know whether reprints are available and what the cost of them will be . . .

MRS. JAMES BLAKE,

President Woman's Auxiliary to the American Medical Association, Hopkins, Minnesota

Typographical Criticisms

To the Editors:

The JOURNAL in its new shape and color looks handsome and is very handy. The paper is good, but the print is abominably poor.

You ask for advice and suggestion: give us larger print. The young will hail it and the old will bless you.

ROBERT ABRAHAMS.

To the Editors:

It affords me considerable pleasure to acknowledge the receipt this morning of the first copy of the new JOURNAL. Your committee deserves well-earned credit for appearance, subject matter, arrangement, and quality of advertising contained in the JOURNAL.

The type and printing is no small part of its general excellence. Like some books, a Journal can be made to "look interesting" and actually invite the reader to scan articles that otherwise would have been left unread.

Kindly accept the sincere congratulations of one member.

EDWARD F. MEISTER, M.D.

THE FEDERAL INCOME TAX LAWS ANALYZED FOR MEDICAL PRACTITIONERS

By LEO T. ABBE, LL B
Certified Public Accountant

It is the purpose of this article to present to the medical profession in a simple and nontechnical manner a method of assembling the financial data and then properly transferring these data to the Federal and State income tax returns.

In order that the reader may determine for himself his own status as a taxpayer, let us see who is required to make a return.

(1) Every individual having a net income for the taxable year of \$1000 00 or over, if single, or if married and not living with husband or wife,

(2) Every individual having a net income for the taxable year of \$2500 00 or over if married and living with husband and wife and

(3) Every individual having a gross income for the taxable year of \$5000 00 or over, regardless of the amount of his net income.

Briefly, if the total amount of the fees and other income is \$5000 00 or over, a return must be filed, *even if after deducting expenses the net income is less than the exemption*.

If the total amount of the fees, plus other income, does not reach the amount of \$5000 00, but after deducting expenses, the net amount is in excess of the exemption, in this case also, a return must be filed.

EXEMPTIONS—The personal exemptions are as follows:

To a person who is single: \$1000 00

To a married person living with husband or wife or to the head of a family: \$2500 00

A husband and wife living together receive one exemption.

If they make separate returns, the exemption may be taken by either, or divided between them.

Credit for Dependents—There is a credit for dependents of \$400 00 for each person under 18 years of age, or incapable of self support because mentally or physically defective.

Where and When Must the Return be Filed—The returns of individuals must be made to the collector of the district in which is located the legal residence or principal place of business of the person making the return. It must be filed on or before the 15th day of March, if the calendar year is the basis of the return. A return based on the fiscal year is to be filed on the 15th day of the 3rd month following the close of the fiscal year.

The return may be reported on either the cash or accrual basis. In most instances the doctor reports on a cash basis, that is, the actual cash received and disbursed during the year, and it is this form of reporting which will be discussed in detail.

The most important feature in the preparation of the return is the analysis of the receipts and deposits as well as the disbursements to distinguish between those items which represent gross income in its accounting and tax interpretation and items which may be a return on capital invested, or a receipt of moneys which represent neither fees nor profits on business deals. Obviously no attempt can be made to distinguish by name the kinds of income in contradistinction to receipts. The test that might be applied in its practical application would be the following question asked in connection with each form of receipts: "Does the amount received represent income or profit in its ordinary sense, or does it represent an exchange of cash for property of similar value relinquished for this cash?"

The difficulty or ease in assembling the receipts data and analyzing their source will depend a great deal upon the detail kept by the doctor. For the purpose of preparing the tax return, the receipts and income should be classified as follows: (1) Income from profession, (2) Interest on bank deposits, notes, bonds, etc. (3) Profit from sale of real estate, stocks, bonds, etc. (4) Dividends on stock. (5) Other income.

There are other receipts besides income which go to swell the bank deposits. Where a proper accounting system is maintained by the doctor, these items will be definitely accounted for. Where, however, the doctor does not earmark carefully each item of receipts, the question of these deposits will return to plague him when the tax departments make inquiry. This practical suggestion is, therefore offered at this time: Prepare a statement of all outside funds, such as exchanges of checks with others, exchanges between banks, deposits in banks which are not income, etc. It is assumed that separate records are maintained to indicate the sources of income. By preparing this record, the income report and the amount of deposits may be reconciled to the satisfaction of the tax agents.

The following items are not to be included in the gross income of the taxpayer:

(1) Life insurance paid upon death of insured. (2) Amount received from endowment policies, except in certain cases. (3) Gifts, bequests, and devises (but the income derived from this property is taxable). (4) Tax-free interest.

The doctor who maintains a proper set of bookkeeping records presumably segregates those items of expense which are (1) wholly professional, (2) partly personal, (3) wholly personal. The doctor who relies upon his check book and supplementary records to establish his expenses for the year must analyze his disbursements with this division in mind.

The classification of expenses would depend a good deal upon the nature of the practice. There are certain expenses, however, which are generally applicable to almost every practitioner, and it is these expenses which will be discussed in detail.

The disbursements may be classified as follows

(1) Rent; (2) heat and light; (3) telephone; (4) laundry; (5) drugs and medicines; (6) minor instruments; (7) assistants and nurses; (8) office payroll; (9) magazines; (10) stationery and postage; (11) dues and subscriptions; (12) call service; (13) repairs of equipment; (14) auto expense; (15) insurance; and (16) depreciation.

Some of these expenses are partly personal, and there is presented in the following discussion, the proper tax application of each of the expense accounts.

Rent.—The payment for rent may be partly personal. The use of the leased premises will govern. Where the practitioner pays rent for office space exclusively, it may be deducted as an expense without further question. Where the doctor rents an apartment, uses part of it as an office and reception room, and the rest as a residence for his family, only part of this rental is a deductible professional expense. That part which is equitably (this does not mean proportionately) chargeable to the office expense should be deducted as rent.

Heat and Light.—A similar equitable division should be made of the heat and light bills for the apartment. Where domestics are employed, if any part of their time is devoted to the service of the office, that part so applied should be charged as a professional expense. It might be noted in this connection, that where the domestic sleeps in, that is, boards and lodges in the apartment of the employer, a similar portion of the maintenance is also deductible.

Where the practitioner owns his own home and uses part of it as an office and reception room, other expenses in lieu of rent would in their division be placed in the same classifica-

tion as rent. Insurance, repairs, and depreciation on the building would be subject to a proportionate division between personal and professional expense. The practitioner who owns his own home receives an advantage which is comparable to the deduction of rent in his authority to deduct as an expense, all interest on mortgage or mortgages, and all local taxes which are not assessments.

Telephone.—Expenses of telephone may be deductible in part or in full dependent upon its use. If the telephone is made available and used by the family for private purposes, only its proper proportion would be deductible as an expense.

Laundry.—If the laundry for the office is kept separate from the home laundry, the bills would be entirely deductible. Otherwise only its fair proportion may be deducted as an expense.

To summarize, where the office and residence are maintained in the same building, only these expenses are subject to division and partially deductible; rent, heat and light, telephone, laundry.

Drugs and Medicines; Minor Instruments, Etc.—The payments for drugs and medicines and minor instruments are deductible in full. Those instruments or parts which have a life of one year or less had best be charged up as minor instruments. Those which have a longer life should be added to the "Instruments Account," the depreciation of which will be taken up later.

Traveling Expense, Autos, Etc.—In the case of traveling expenses, auto expense, etc., undertaken for business purposes, there may be taken as an expense railroad or bus fares, meals and lodging as well. Incidentally, all traveling expenses, including railroad fare and hotel bills attending a medical convention may be deducted as a business expense.

The practitioner who maintains an automobile for professional purposes may deduct the cost of gas, oil, supplies, garage, repairs, insurance, and any other expenses resulting from its operation. He may also include a charge for depreciation on the car. Where the auto is also used by the family for other than professional purposes, the same degree of care must be exercised in apportioning the expense for tax purposes.

Dues or memberships to professional societies as well as trade publications are deductible. In the case of expense for magazines placed in the waiting room for the patients, where the purchase is made expressly for this purpose, it is also deductible.

Payments for equipment should be spread over the probable life, and a proportionate charge, otherwise known as depreciation set up

for each year or period. Where the equipment, in spite of its condition, becomes obsolete for all practical purposes, the balance not previously charged off is considered as an expense for the year in which it becomes obsolete.

The same principles of depreciation would govern the payments for *office furniture and books*.

In passing, it is recommended that a memo book be maintained in which would be indicated the date of purchase, name of equipment, and price paid therefore, so that inquiry on the part of the tax agent to substantiate the amount of depreciation would find the doctor prepared to justify it.

The test of the deductibility of any expenditure not properly identified with the above grouping would be its relation to income producing to the profession as well as absence of personal or living expense.

As a practical guide to the analysis outlined above, it is suggested that a columnar sheet be headed up for each group to a column. Items paid once a month such as rent, heat and light, etc., might all be grouped in the first two columns. The last column would be headed "personal expense." Then transfer from the check stubs to the proper column. This will provide an accounting of the expenses paid for by check. Further inquiry and reference to petty cash data will supply the information of the expenses paid for by cash.

PAYMENT OF TAX: (a) Time of Payment.—The tax must be paid by the 15th day of March following the close of the calendar year, or if the return is made on the basis of the fiscal year, then it is due on the 15th day of the third month following the close of the fiscal year.

(b) Instalment Payments.—The taxpayer may, if he chooses, pay the tax in four equal instalments, as follows:

March 15th	25 per cent of the tax
June 15th	25 per cent of the tax
September 15th	25 per cent of the tax
December 15th	25 per cent of the tax

If, however, he is reporting on a fiscal year, he pays as follows:

- 25 per cent of the tax when the report is due.
- 25 per cent of the tax on the 15th day of the third month following.
- 25 per cent of the tax on the 15th day of the sixth month following.
- 25 per cent of the tax on the 15th day of the ninth month following.

Where the taxpayer elects to pay the tax in four equal instalments, he should make note in his daily office diary. The Collector of Internal Revenue does, however, send a slip as

a "reminder" in the form of a bill which should be enclosed with the check in payment and returned to the same office where the return was filed.

GENERAL PROBLEMS.—The following observations probably cover most of the inquiries with respect to the filing and Federal taxability of the income, professionally and otherwise.

(1) The taxpayer and his wife may elect to file either a joint return or individual returns. This election may be made each year. The amount of exemption may be divided by them as they see fit.

(2) The expense of a postgraduate course is a *personal* one and *not* permitted as a deduction.

(3) The profit on the sale of State or Municipal bonds is taxable. The interest received on State or Municipal bonds need *not* be included as income.

(4) Commuters' fares to the office are a personal expense and not deductible.

(5) In the case of a doctor who rents a property for residential purposes but incidentally receives patients in connection with his practice (his office being elsewhere), no part of the rent is deductible.

(6) The doctor cannot deduct as contributions the value of services given gratis to patients.

(7) Interest or service charges for the discounting of patients' notes are deductible as an expense.

(8) Losses on securities: (a) Securities held more than two years: losses may be deducted in full. The reduction in tax, however, because of this loss is limited to 12.5 per cent of the loss sustained.

(b) Securities which have become wholly worthless are deductible in the year in which they become worthless. The cost is deductible as a loss.

(c) Securities held less than two years: The losses on these securities may be offset against a similar amount of profits on securities held less than two years. The *excess of profits is taxable*. The *excess of loss is not deductible*.

If these securities are bonds of governments or subdivisions of governments, domestic or foreign, the losses may be deducted in full.

The State of New York Income Tax Law does not distinguish between securities held for more than two years and those held for a lesser time. The above rules would not apply in determining the profit or loss of securities for State Income Tax purposes.

MEDICOLEGAL

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York.

Legal Practice of Medicine—Diagnoses Held Violation of Statute

ORGANIZED medicine has for years been forced to combat with attempts on the part of laymen to engage in the practice of medicine under one guise or another. A decision handed down recently by the highest court of one of the Mid-western States, dealt a severe blow to lay organizations undertaking to render diagnostic medical work.

A certain layman, G—, had conducted what was called a "health audit." The procedure followed was that for a fee of \$10 a year he undertook to furnish to his so-called "subscribers" four urinalyses and a blood pressure test. The patients would send him samples of urine, usually by mail, and they would be turned over to a certain duly licensed pathologist, Dr. A—, who was under contract to G—. Analysis would be made and the findings given back to G—. If serious abnormalities were found, G— would advise the subscriber to consult a competent physician for treatment, but if the abnormalities were slight, he would give out advice as to proper diet, habits and exercise. The report of the health audit, concededly, never advised the taking of any other form of treatment, and never advised as to drugs or medicines.

The State Board of Medical Examiners investigated the practices of G—, and advised Dr. A— that G— was engaged in illegal medical practice, and directed that Dr. A—, the pathologist, desist from making urinalyses in accordance with his contract with G— on the ground that it was illegal for him to do so. Suit thereupon was brought by G— against the State Board to enjoin them from interfering with the operation of the contract which he had made with the pathologist. His complaint was dismissed by the District Court, and the matter was taken up on appeal.

The high Court concluded that the record showed a case of illegal medical practice, and affirmed the ruling of the lower Court, thereby approving the action taken by the Board of Medical Examiners. In its opinion the Court said:

"In our opinion, advising the subscriber for a fee as to certain improved habits of diet, exercise or living, although not accompanied by any medical prescription or treatment is a violation of section 5717 (which prescribes the penalty for practicing without registration). Diet, exercise and mode of living are agencies for the relief of disease. Indeed, they are the only known relief or treatment of some diseases. It further appears that the urinalyses and blood pressure tests are important as indicating the condition of a patient's health, and when an abnormal condition is indicated, the opinion of the pathologist is passed on by the plaintiff to his subscriber.

"In his complaint the plaintiff sets out some twenty-two items whose presence, absence or quantity must be considered in determining the result of the analysis. The analysis and the test form a basis for a diagnosis. Necessarily the question of whether the analysis results in indications showing normal or abnormal conditions is a matter of professional medical opinion. Deductions must be drawn from the result of the analyses, and these deductions are of value only when made by a medical man. It cannot be otherwise. The pathologist is, of course, a licensed physician, and in this case is said to be an expert in his line. Obviously, if he were in direct contact with the subscriber as a patient, he would be practicing medicine in doing exactly what the plaintiff hired him to do. The results of his work the plaintiff passes on to his subscribers.

"If Dr. A— was practicing medicine in what he did and in determining for the plaintiff whether the condition of the urine was normal or abnormal, then, in our opinion, the plaintiff was practicing medicine when he passed on to his subscribers the result of the analysis and the advice of the pathologist. It was as much practicing medicine for the plaintiff to engage Dr. A— to do this for him as it would have been if he had attempted himself to perform these analyses, as he in fact did in the case of the blood pressure tests. To pass on to his subscribers advice as to whether or not the tests indicated a normal or abnormal condition, and whether or not the subscriber should consult his physician or be content with the advice which plaintiff might give in regard to diet, exercise, or mode of living was practicing medicine."

The Court pointed out it had already held in a former case that a corporation or layman could not practice law indirectly by hiring regularly qualified lawyers to do the work for them. It continued in the opinion:

"We are just as firmly convinced that it is improper and contrary to the statute and public policy for a corporation or layman to practice medicine in the same way. The obligation of Dr. A— under his contract was to plaintiff not to the subscribers. Plaintiff might engage anyone to perform these analyses. What the law intends is that the patient shall be the patient of the licensed physician, not of a corporation or layman. The obligations and duties of the physician demand no less. There is no place for a middleman."

In support of the determination that diagnosis alone amounts to the practice of medicine, reference was made to a case decided some fifteen years before. In that case a chiropractor was convicted of practicing medicine without a license on proof that the offender had made a physical examination of a

patient, diagnosed an abdominal tumor, and for that condition had recommended an operation by some competent surgeon. In the earlier case the Court had said:

"The science of diagnosing human diseases and human ailments has come to be a distinct branch or department of the medical profession; the diagnostician limiting his efforts to a discovery of the disease or ailment from which a patient may be suffering; its character and location, leaving the treatment thereof to some other physician or surgeon. This is a matter of common knowledge. And it requires no discussion or argument to demonstrate that the physician who thus applies his learning and energies is performing a highly important duty of the profession and is engaged in the practice thereof though he prescribes no drug and administers no specific treatment."

The result arrived at by the Court is indeed gratifying. The decision is in harmony with reason and with sound public policy.

Claimed Negligent Herniotomy

An elderly man consulted a surgeon regarding a hernia from which he was suffering. The patient gave a history that while he was taking chiropractic treatments several years before, he had felt something snap in his right side with terrific pain resulting and that ever since that time he had experienced a swelling in his right groin on coughing. He had worn a truss for three and one-half years and during the few months prior to consulting the doctor the hernia had caused him considerable annoyance, and that it was difficult on many occasions for him to reduce the hernia.

The doctor examined him and found the right inguinal ring enlarged with a mass protruding through the canal. He advised operation, to which the plaintiff consented. During the performance of the operation, after making the incision, the doctor found a large mass of indurated fatty tissue around the cord. He decided that this tissue if allowed to remain would make a recurrence of the hernia more probable and removed the tissue, which involved a long tedious and difficult procedure. The doctor attended the patient during his period of convalescence and during one stage of the aftercare made a small incision to determine whether any fluid had accumulated at the site of the operation or whether any infection had developed. No discharge was obtained upon making this incision. The patient reported to the doctor on one occasion that he had removed what he termed a piece of string that protruded from the incision. He exhibited same to the doctor who put it under a microscope

and determined that it was a bit of fascia rather than any foreign substance. The patient went under the care of another doctor who some time later drained an abscess that developed at the site of the operation.

An action was brought against the surgeon, charging him with malpractice in making the claim that in the performance of a right inguinal herniotomy on the plaintiff the defendant left in the plaintiff's abdominal and pelvic cavities a gauze sponge and that as a result of said claimed negligence the plaintiff's condition did not improve properly and that he was obliged to undergo subsequent surgical treatment. Before the case came up for actual trial the plaintiff died from cancer of the stomach and the action against the doctor therefore abated.

Alleged Negligent Operation of the Right Eye

An eye specialist was consulted by a woman about 42 years of age. She complained of pains in her eyes. The diagnosis was cataracts of each eye and an operation was suggested, to which the patient consented. About a week later the patient entered a hospital and under a local anesthesia the following operation was performed: The iris was incised and the necessary muscle removed.

About five weeks later the patient returned to the hospital and under local anesthesia the doctor went in under the cornea and extracted the lens. The incision was sutured and bandages applied to both eyes and the patient remained in the hospital ten days. The doctor saw her daily and the wound healed nicely. At the end of ten days she was permitted to go home. The doctor saw her daily at his office for about three weeks, toward the end of which time he discovered that a membrane had formed over the pupillary area. The patient was sent back to the hospital, the membrane was needed and this condition was corrected. Approximately one month after the operation the final examination revealed that the vision in the right eye with glasses was 20/30, and the old cataract was present on the left eye with vision 10/200. The doctor then told her to come back and that he would operate upon the left eye. She never returned.

Thereafter a bill was sent to the patient and a small payment on account was made. The doctor sued for the balance due and a counterclaim was interposed alleging malpractice.

The case duly came on for trial and at the start of said trial the defendant consented to a discontinuance of the counterclaim and a judgment was rendered in favor of the doctor.

Death Due to Status Lymphaticus

A girl of 16 who was employed in a factory injured her foot when it was struck by the point of a pair of scissors that dropped upon it. She consulted a certain physician who on examination found that she had a punctured wound and laceration on the dorsum of the foot. The doctor applied a wet dressing of chloramine and a sterile gauze pad and then bandaged the foot. He also injected into the arm of the patient 15 units of tetanus antitoxin. The preparation which he so used had been obtained by him in ampule form from the local board of health. The injection was made with the usual antiseptic precautions. The patient left the doctor's office, and the next he heard of her was that within an hour or so after she left his office she had dropped dead on a nearby subway platform.

An autopsy was performed by the medical examiner who reported the death was caused by status lymphaticus.

An action was brought against the doctor by the administrator of the decedent, charging that negligence on the part of the doctor caused the death.

The case came on for trial before a judge and jury and after the issues had been submitted to the jury a verdict was rendered in favor of the defendant.

Treatment of Injuries to Hand Sustained in an Accident

A young woman was brought to the accident ward of a hospital shortly after she had been injured in an automobile accident. The chief surgeon in attendance at said ward examined her and found that she had a compound fracture of the first, second and third metacarpal bones of the left hand, severe lacerations of said hand and cut tendons, with subcutaneous hemorrhage of the hand and forearm. An x-ray picture was taken, which confirmed the said diagnosis. The patient was put under general anesthesia and the fracture reduced. The doctor drew the tendons together and sutured them. Three incisions were made in the hand and forearm and blood clots were evacuated and drainage instituted. The patient was given an injection of 1500 units of tetanus antitoxin. The doctor put the hand in an anterior splint and bandaged it lightly. The patient remained in the hospital over night and he saw her on the following day. Her condition was good and the swelling had gone down somewhat. He did not disturb the splint and left the patient in charge of the house surgeon. That same afternoon the surgeon who had treated her received a call from a certain doctor connected with another hospital who said he wanted to take over the care of the patient. The surgeon consented and the patient was taken away from the hospital. The surgeon never saw her again.

The next he heard of the matter was when he was served with a summons and complaint instituting a malpractice action against him, charging that he was negligent in his treatment and that he had caused an infection to

develop and that the patient had sustained a permanent impairment of function of the left thumb and loss of power in the fourth and fifth left fingers.

An answer was interposed in the action on behalf of the doctor and some time later investigation revealed that the plaintiff before she brought her action against the doctor had instituted an action in the Supreme Court against the owner and operator of the automobile as a result of whose negligence she had sustained her original injury. The said action against the automobile owner had come on for trial and a verdict had been rendered in favor of the plaintiff in that action in a substantial sum. An application was made to the court permitting the defendant in the malpractice action to set up as a defense in his answer the fact that the plaintiff had been compensated for her injuries in the automobile accident. Shortly after the said defense was interposed in the malpractice action the plaintiff's attorneys consented to discontinue the action.

Particle of Steel in Eye

A man who had been working on an automobile appeared at the clinic of an eye and ear hospital and stated to the doctor in attendance that he thought he had gotten something in his eye.

The doctor examined his eyes carefully, using an electric bulb and was unable to discover anything. He put some dilating drops in the patient's eye and gave him a requisition for x-rays in the x-ray department of the hospital, explaining to the patient that he should immediately go to said department and return after the pictures were made. The doctor never saw the patient again. The patient several days later went to the hospital's x-ray department and obtained the pictures which revealed the presence of a tiny foreign particle 0.75 by 1 mm. in size, located 12 mm. back, 11 mm. nasal side, 3 mm. below center.

The case had been reported to the insurance carrier for the man's employer as an industrial accident covered by workmen's compensation. The insurance carrier referred the patient subsequently for x-ray examination to his own doctor who put him in a hospital and by the use of a magnet drew from his eye a particle of steel about the size of the head of a pin. The patient lost a considerable degree of the sight of the said eye.

The patient instituted action against the doctor who first examined him, charging him with negligence in failing to discover the foreign body.

After the action was started, however, the plaintiff failed to bring the same on for trial. After some time had elapsed a motion was made to dismiss the case for lack of prosecution which was granted by the court at special term, thereby terminating the matter.

Books Reviewed

THE CLINICAL ASPECT OF CHRONIC POISONING BY ALUMINUM AND ITS ALLOYS—By Ico Spira, M.D. Octavo of 28 pages, illustrated. London: John Bale Sons & Danielsson Ltd., 1933. Paper 2/6.

This is a small pamphlet in which the author describes certain gastro-intestinal and cutaneous disturbances which he contends are the result of using aluminum utensils in the kitchen. The observations of the author are limited to cases occurring in Austria, Czechoslovakia and England.

In this country during the past few years there has been considerable agitation over the possibility of poisoning by aluminum compounds used in the manufacture of food. To those interested in this subject, this pamphlet may be of value. A fairly complete bibliography is appended to the article. S.

PROSPECTING FOR HEAVEN—Some Conversation About Science and the Good Life. By Edwin R. Embree. Octavo of 185 pages. New York, The Viking Press, Inc. Cloth \$1.75.

The strict scientist lives in a world of realities. When he speculates it is for the purpose of converting ideas into facts. One may, however, talk about science in an abstract way not to seek facts but to ask himself the question—"Wherefore?" He soon finds himself in a super natural world or in the words of the author—"Prospecting for Heaven."

The dinner table seems to afford an ideal setting for such discussions. At that time we are apt to depart from realities and theorize. And so we may talk about the "dark of the mind" or of "curiosity" or of "the art and science of living together" or of "feeble and faltering minds." Eight individuals, only one or two being physicians (psychiatrists), participated in furnishing the author with the material for this book. To the practitioner trained in the school of grim realism such a book may not register a sympathetic response. It should find its appeal among students of psychology.

EMANUEL KRIMSKY

HOW TO BUDGET HEALTH—By Evans Clark. Octavo of 328 pages, illustrated. New York, Harper & Brothers 1933. Cloth \$4.00. (Published for the Twentieth Century Fund.)

This volume of three hundred pages is a report on a three-year investigation of group practice conducted under the auspices of the Twentieth Century Fund. According to the preface it is intended to be "A sort of sequel to the report of the Committee on the Costs of Medical Care." It describes collective methods of supplying medical service to the people—groups of physicians dealing with groups of people, in distinction from individual doctors serving individual persons. Its first six chapters contain encyclopedic information regarding groups, guilds, and insurance societies which are in actual operation. Then come five chapters on the problems of organizing groups first of physicians and then of persons who are prospective patients.

Chapter 12 quotes the opinions of seventeen physicians regarding group medical service, and chapter 13 gives similar opinions of 1500 laymen who were interviewed.

The reader would do well to turn to Chapter 11 first, for it is a concise analysis of the contents of the previous chapters.

This book is predominantly informational, with a conspicuous absence of propagandism. It closes with a plea that those who wish to organize a group for giving collective medical service should join with physicians in making a thorough study of the problem in that particular community.

FRANK OVERTON

SURGICAL ANATOMY—By C. Latimer Callender, M.D. Quarto of 1,115 pages, illustrated. Philadelphia: W. B. Saunders Company 1933. Cloth \$12.50.

This volume, consisting of 1,115 pages with 1,280 illustrations, is well bound and printed on excellent paper with a clear, large type. The work is an entirely new one. It differs from the usual textbook of anatomy in that the clinical manifestations of the subject under discussion are included. It has none of the characteristics of the usual uninteresting presentation of the subject of anatomy. It differs from the previous textbooks on surgical anatomy and on surface anatomy in that it is much more comprehensive and inclusive.

The general plan is to present the anatomy of the organ of the region under discussion, and then to discuss its surgical application. Dr. Dean Lewis has written the foreword, in which he states that the paths of surgical approach to the pathologic process are indicated.

Only anatomical facts which have some clinical importance are discussed. The reviewer knows of no similar book or books which, in any way, can be compared to this one. Because of the interesting method of presentation, and because of the completeness of the material included, the book is recommended most highly, not only to the surgeon, but to the medical student and the internist.

MERRILL N. FOOTE

POLIOMYELITIS—A survey made possible by a grant from the International Committee for the Study of Infantile Paralysis. Octavo of 562 pages, illustrated. Baltimore, Williams & Wilkins Company. Cloth, \$6.00.

This publication contains the results of a three-year study of poliomyelitis by the International Committee for the Study of Infantile Paralysis. The material is grouped under the following headings: Historical summary, Etiology, Resistance and Immunity, Symptomatology, Epidemiology, Pathology and Treatment, each chapter being written by a special contributor. The publication presents all the information on the subject available at the time.

The volume will serve as a valuable reference book for many years and should be in the possession of everyone interested in this subject.

MURRAY B. GORDON.

TEXTBOOK OF PHYSICAL THERAPY.—By Heinrich F. Wolf, M.D. Octavo of 409 pages, illustrated. New York, D. Appleton-Century Company, [c. 1933.] Cloth, \$5.50.

The book consists of twenty-eight (28) chapters, in the first nine of which the author gives the theory and principles of Physical Therapy. The chapters on Massage and Hydrotherapy stand out pre-eminently.

From chapters ten (10) to twenty-eight (28) the author brings us through the varied systems of the human anatomy and other varied miscellaneous subjects and shows wherein Physical Therapy is of value and its mode of use. Among these chapters the one on Fractures predominantly stands out and in our estimation should be of inestimable value to the Orthopedist and to the Surgeon (practicing fracture work).

The remaining five chapters consist of two by William Bierman, M.D. Hyperthermia is the subject of one upon which he is an authority. He writes well, is readily understood, but his subject is a highly debatable one and needs considerable more work and time before being placed on a definite basis. His subject in the other chapter, Minor Electro-Surgery, is good, to the point, well written and worth reading.

The chapter by Adolph L. Lillien, M. D., covers ten pages for the Diseases of the Lower Respiratory Tract. Indeed short for a large subject.

The chapter by Farel Jouard, M.D., Physical Therapy in Otolaryngology, seems to cover the field well in the allotted space. His preference for the use of surgical removal of tonsils is absolutely evidenced by his inadequate explanation of his method of removal by electrocoagulation.

Madge L. McGuinness, M. D., writes an interesting final chapter on Physical Therapy in Gynecology. Her chapter is very limited but contains many good points.

The book shows the widespread possibilities for using the modalities of Physical Therapy in the treatment of disease. It definitely points out that this science is necessary and its measures should be used with other therapeutic means, in general practice and in the specialties.

JOHN J. HAUFF.

THE TREATMENT OF RHEUMATISM IN GENERAL PRACTICE.—By W. S. C. Copeman. Octavo of 215 pages. Baltimore, William Wood & Company, 1933. Cloth, \$3.25.

The writer discusses acute rheumatic fever and its treatment. Then under separate chapters he discusses acute myositis and fibrositis, sciatica, neuritis, the various arthritides and spondylitis. The term rheumatism in the title will probably lead to confusion in the minds of many. In the treatment of the latter group of conditions, thorough discussion is given to the various drugs such as thyroid, iron and arsenic. The importance of a proper state of nutrition and well balanced diet—sufficient calories for the mal-nourished, and the reduction of weight for the obese is stressed. Vaccines and non-specific protein therapy are dis-

cussed, but no great results are predicted. Physical methods, such as exercise and manipulations, are gone into in great detail. While there is nothing new, there is considerable detail in treatment. This little volume makes very easy reading.

M. A. RABINOWITZ.

PSYCHOANALYSIS AND MEDICINE.—A study of the Wish to Fall Ill. By Karin Stephen, M.A. Octavo of 238 pages. New York, The Macmillan Company, 1933. Cloth, \$2.50.

The book is based on a series of eight lectures delivered mainly before medical students at Cambridge. The titles of the eight chapters indicate the subject matter under discussion. In the first chapter, there is an explanation of the origin of the unconscious in disappointment and an elucidation of the nature of conflict and repression. In the next chapter the obstacles in the way of investigating the unconscious, and the use of psychoanalytic free association technique are presented. The primitive sexual nature of the unconscious is given in chapter four. Another chapter is devoted to the infantile pleasure seeking by the mouth. A chapter is devoted to the excretory pleasure seeking and its relation to creation. The phallic pleasure seeking, the Oedipus complex, and castration fears are treated in one chapter. Anxiety and guilt are treated together. Primitive mental mechanisms, defense mechanisms, and the use of transference in treatment are discussed in the final chapter.

The book is a fine presentation of the psychoanalytic theory and technique, well written and quite thorough.

IRVING J. SANDS.

ALLEN'S COMMERCIAL ORGANIC ANALYSIS.—Edited by C. Ainsworth Mitchell, D.Sc. Volume X, Fifth Edition. Octavo of 817 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, [c. 1933.]

The entire set of ten volumes is a treatise on the properties and modes of analysis of the various organic chemicals and products employed in the arts, industries, commerce, science and medicine. Volume ten is a comprehensive source book dealing with hemoglobin and its derivatives, albuminoids, structural proteins, vitamins, hormones and pectins.

The contributors are all British authorities. It is an excellent reference book, well written and up to date. The clinician will find of particular value the chapters on vitamins and hormones. Professor Drummond, who has contributed the chapter on vitamins, describes the chemical nature of the vitamins, biological tests for their detection, care of the test animals, method of their quantitative estimation, symptoms of vitamin deficiency, vitamin standardization and therapy.

The chapter on hormones is written by Culhane and Underhill and contains excellent surveys of thyroxine, parathormone, adrenaline, insulin, pituitary hormones and gonadotropic

hormones, with complete descriptions of their constitution, preparation, extraction, properties, derivatives, physiology, pharmacology and methods of assay. These chapters are infiltrated with extensive bibliographic references.

WILLIAM S. COLLENS.

THE ENLARGED PROSTATE AND PROSTATIC OBSTRUCTION—By Kenneth M. Walker, I.R.C.S. Second Edition. Octavo of 223 pages, illustrated. New York, Oxford University Press, 1933.

The new edition of this little book covers the whole subject of the surgery of bladder neck obstruction, including the more recent transurethral procedures in a very concise form.

While of course it would be impossible to cover such a large subject exhaustively in such a small volume, there is a great deal of information condensed in a small space. The writer is a well known clinician with a very large experience and his book clearly reflects his intimate familiarity with all the problems involved. It is heartily recommended to the general practitioner who desires to cover briefly an up-to-date review of the problems of prostatism.

It is easy reading and I think that the specialist would thoroughly enjoy an evening spent in reading it.

N. P. RATHBURN.

ESSENTIALS OF PRESCRIPTION WRITING—By Cary Eggleston, M.D. Fifth Edition. 16mo of 155 pages. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$1.50.

This is an excellent, well-written, instructive volume upon a subject which receives but little attention in the curriculum of the medical college. The importance of proper prescription writing is emphasized and numerous examples are presented.

The fact that the demand for this book has compelled frequent editions of the work attests its value. It should be studied by all who prescribe drugs.

HENRY M. MOSES.

SURGERY OF THE STOMACH AND DUODENUM—By J. Shelton Horsley, M.D. Octavo of 260 pages, illustrated. St. Louis, C. V. Mosby Company, 1933. Cloth, \$7.50.

To speak in the old-fashioned review manner one would say: This book covers adequately the surgery of the stomach and duodenum. It is written by a master surgeon with knowledge of the recent physiologic work on the gastro-intestinal tract. It represents personal experience. It not only describes common but unusual clinical symptoms and correlates the symptoms and operative technique with the physiologic facts. Extensive operations are described in detail. Professor Harvey E. Jordan of the University of Virginia gave the author assistance in the preparation of the chapter on Embryology, Anatomy and Physiology.

But, in the modern review one wishes to give more than the old-fashioned technical views. Here is a book that from the dedication to the final word is interesting and instructive. It breathes the personality of the author, a man whose life has been dedicated

to the study of surgery as an art. To those who know the author and him to whom the work is dedicated there is recalled the cheering hospitality of these wonderful Southern Gentlemen who combine in themselves all those graces of background, art and science which go to make up the perfect master surgeon.

Here is a book you can read from cover to cover and will not care to lay down until you have finished it. The young men can gain lessons in experience from it, the older surgeon can refresh and broaden his mind by comparisons which naturally occur as the pages are turned. It is recommended to all. It will make a great gift for the Chief to give his assistants.

RUSSELL S. FOWLER.

PEDIATRICS—By Henry Dwight Chapin, M.D. and Lawrence T. Rovner, M.D. Seventh Edition. Octavo of 775 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$7.00.

This one volume "Pediatrics" is a very satisfying book. The whole subject is covered briefly, clearly and yet completely as may be seen by perusing the table of contents. We miss only the unimportant controversial points and the distracting repetition of case report statistics of which most books are too full. The important controversial matters are given with editorial comment. All unnecessary subjects have been omitted with the exception of Addison's Disease. And why this is included in a book of Pediatrics we are still at a loss to understand.

The arrangement of subjects is excellent. There is a complete index and in general the book will serve well the medical student as a text book and the general practitioner as a book of ready reference. We have thoroughly enjoyed reading the book from cover to cover in preparation for this review.

Dr. Chapin's Speedwell Plan for the care of dependent convalescent children is especially praiseworthy, deserving wide publicity for the purpose of stimulating more frequent imitation.

K. G. JENNINGS.

Cancer

What Everyone Should Know About It. By James A. Tobey, Dr. P. H. O. Octavo of 313 pages, illustrated. New York, Alfred A. Knopf, 1932. Cloth, \$3.00.

This book is remarkable for more than one thing. In the first place it has two introductions; one by H. L. Mencken and one by J. C. Bloodgood. One of these is sincere—it begins "In a few years, I hope and suspect Doctor Tobey's book will have to be rewritten." Some of it could be rewritten now. It carries embedded in its matrix that belief in propaganda, in publicity, in ballyhoo, that was a part of the first phase of the attack on cancer. The public should be told about cancer as much as their tender nerves could bear, and to the end of such education the various techniques of the salesman should be mobilized and set to work.

Unfortunately the layman having become interested in cancer has begun to investigate for himself and in scrutinizing the statistics offered him just as you and I investigate the claims of the latest cancer cure.

Doctor Bloodgood, for instance, says on page XXVII, "in one of the largest clinics of this country in 1915, the actual cures (sic) of cancer of the stomach by resection were less than two per cent, today the actual five year cures (sic) are reaching twenty-five per cent in a large number of clinics." Phooey! The Public knows better than that, you and I know better than that and Joe Bloodgood knows better than that and should have intelligence enough to know that false representation is bad salesmanship. It is the truth that fully half of the cases of cancer are incurable when, in the present state of our knowledge and skill, they are—not recognized, but recognizable. That what is now most needed is not knowledge on the part of the patient but knowledge that nobody has. That more intense and distributed research seems the only hope and that false optimism, in this as in so many other fields, will be followed by loss of confidence and despair. It is true that cancer is now recognized too late. Some of this is the fault of the patients' ignorance and neglect. Some of it is due to the neglect and ignorance of the physician. Both should be instructed. It is also true that the cancer victim at present must often run the gauntlet of cruel, expensive and futile therapy before his inevitable release.

The attack on cancer has entered its second phase which is or should be a shift from ballyhoo to organization—an attempt to put, where the victim can get it, material, skill and support in his dire need.

In spite of all of which the book is an excellent historico-novelistic "readable" account of the attack on the idea of cancer. Old stuff! Time to come down to earth. Time to deal with the man who owns one, in honesty and faith.

JOHN E. JENNINGS.

CASE STUDIES IN THE PSYCHOPATHOLOGY OF CRIME.—By Ben Karpman, M.D. Vol. 1. Large octavo of 1042 pages, illustrated. Washington, Mimeograph Press, [c. 1933.] Cloth, \$12.00. (The sale of this book is restricted to members of the medical, legal, scientific and other professions having a direct and definite interest in medical and social problems.)

The book consists of five cases studied in great detail. The cases include an evaluation of the early life, the home life, the relationship within the family group, army and civil experiences, as well as social maladjustments. In addition there is a complete report with respect to the general picture presented at the hospital.

Each case is exhaustively discussed from a dynamic point of view.

In studying these cases in a longitudinal section, one is able to weave into a single structure, the psychopathological difficulties encountered by the patient.

The method indicates the scientific approach in understanding anti-social behavior.
GEORGE I. SWETLOW.

ROSE AND CARELESS MANUAL OF SURGERY.—Fourteenth Edition. Revised by Cecil P. G. Wakeley, D.Sc. London, and John H. Hunter, M.C. American (Fourteenth) Edition edited by W. T. Coughlin, M.D. Octavo of 1468 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$9.00.

The fourteenth, or American edition, of this text has been re-arranged for American needs by W. T. Coughlin, working in conjunction with the editor. The purpose of this American edition is to provide for the student of medicine a text in surgery which will permit him to qualify in that department as a good general practitioner.

To accomplish this purpose much superfluous matter has been omitted from the American edition. There has been little attention paid to fads and fancies in surgery and only those matters of tested value have been given space.

All subject matter has been brought up to date. Although the book is not a monographic work, several authors have contributed to its production.

The fourteenth edition of Rose & Carless (the American edition) well deserves a place on the bookshelf of the student and surgeon.
ROBERT F. BARBER.

DOUBT. A Study of Knowledge. By Charles F. Howland. 12mo. of 410 pages. New York, Newhill Company, [1933.]

This book consists of six chapters with notes and a bibliography that make this a text rather than "just a book." This volume requires more than mere reading. It requires study. One is carried back to the days when he studied physiology under Professor John C. Cardwell. How he stressed the value of thought, doubt and discussion. So, does this book bring out the value of these factors in epistemology.

The notes and bibliography are replete with names such as Aristotle, Galileo and others down through the ages to our present day.
SAMUEL ZWERLING.

DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS.—By George W. Norris, M.D. & Henry R. M. Landis, M.D. Fifth edition. Octavo of 997 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$10.00.

This edition of a work which is now a standard one, has an addition of 21 new subjects, with 30 others entirely rewritten. As in previous editions, the aim is to teach the old and well established methods of diagnosis, instead of the newer laboratory procedures. There are many illustrations, some from frozen sections of the cadaver previously hardened in formalin, and these are excellent.

The book is a large one and many of the sections are extensive, especially the one on the diseases of the bronchi, lungs, pleura and diaphragm. It is a valuable reference book, thoroughly revised.

WILLIAM E. MCCOLLUM.

**THE DIAGNOSIS AND MANAGEMENT OF CARCINOMA
OF THE COLON AND RECTUM**By **FRANK H. LAHEY, M.D.**
*Boston, Massachusetts*Read at the Annual Meeting of the Medical Society
of the State of New York at New York City, April 4, 1933

CANCER of the colon and rectum is a far from hopeless lesion. On the contrary, there are several features about malignancy in these locations which should encourage us to continue trying to cure an ever-increasing percentage of these cases.

As is shown in Table I, out of 270 carcinomas of the colon and rectum, 202, or 75 per cent, occurred somewhere between the sigmoid and the rectum. Carcinoma of the sigmoid and rectum is notably benign in character. Many of the lesions undoubtedly begin as benign adenomata and then become malignant adenomata with a relatively low degree of malignancy. Fortunately, the sigmoid and rectum, being an intestinal level intended for the storage of feces, are equipped with a relatively scanty number of lymphatics. Since, also, it is the function of this segment of the large intestine to act as a storage reservoir,

TABLE I—SITE OF CARCINOMA OF LARGE INTESTINE IN
270 PATIENTS

Cecum and ascending colon	36	13 per cent
Hepatic flexure	12	
Transverse colon	15	
Splenic flexure	5	
Sigmoid and descending colon	58	22 per cent
Rectosigmoid	37	
Rectum	107	53 per cent
Sigmoid to rectum	202	75 per cent

relatively little fluid absorption goes on at this level. It is readily possible, by means of digital, proctoscopic, and sigmoidoscopic examination, as well as by bismuth enemata and laboratory examination of the stools, to make quite positive and early diagnoses of lesions in this region. In addition to that, it is anatomically possible to radically remove all parts of the colon, including the rectum and lower sigmoid together with their adjacent lymph glands. All of these factors should encourage us to try and obtain better results in carcinoma of the colon and rectum than we have assumed were possible.

From the point of view of symptoms and from the point of view of technical difficulties in operative procedures, the large intestine

may be divided into three segments: (1) the proximal colon, extending from the cecum up to, and past, the transverse colon; (2) the distal colon, extending from the splenic flexure and transverse colon down to the rectosigmoid junction; and (3) the rectum.

The function of the proximal colon plays a considerable part in the character of symptoms produced in the presence of malignant lesions at this level. The proximal colon is rich in lymphatics. It is a level at which fluid absorption goes on to a marked extent. Because the character of its contents is fluid, they tend to be rich in organisms of a high virulence, probably due to the fluid character of the media producing favorable cultural conditions. Because, also, of the fluid character of the contents of the right colon, intestinal obstruction tends not to occur here. Also, because of the fluid character of the intestinal contents here and the presence of organisms of high virulence, operative procedures on the proximal colon are extremely dangerous from the point of view of contamination, spreading of infection, and the production of general peritonitis.

The distal colon, on the other hand, extending from the splenic flexure to the rectosigmoid junction, possesses relatively little fluid-absorbing function. It contains feces of solid character, and so tends not to harbor numerous organisms of a high virulence; it is less rich in lymphatics because of its storage function as compared with the right colon; and because malignant lesions at this level tend to be annular in type, together with the fact that its contents are solid, the symptoms of intestinal obstruction occur much earlier and are of more marked character than in malignant lesions of the right colon.

Lesions of the rectum, occurring in the bowel from the rectosigmoid junction to the anus, due to the fact that this intestinal segment is almost without function except that of storage, may and, in fact, are frequently of quite silent character. Not infrequently,

Unfortunately the layman having become interested in cancer has begun to investigate for himself and in scrutinizing the statistics offered him just as you and I investigate the claims of the latest cancer cure.

Doctor Bloodgood, for instance, says on page XXVII, "in one of the largest clinics of this country in 1915, the actual cures (sic) of cancer of the stomach by resection were less than two per cent, today the actual five year cures (sic) are reaching twenty-five per cent in a large number of clinics." Phooey! The Public knows better than that, you and I know better than that and Joe Bloodgood knows better than that and should have intelligence enough to know that false representation is bad salesmanship. It is the truth that fully half of the cases of cancer are incurable when, in the present state of our knowledge and skill, they are—not recognized, but recognizable. DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS.—By George W. Norris, M.D. & Henry R. M. Landis, M.D. Fifth edition. Octavo of 997 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$10.00.

This edition of a work which is now a standard one, has an addition of 21 new subjects, with 30 others entirely rewritten. As in previous editions, the aim is to teach the old and well established methods of diagnosis, instead of the newer laboratory procedures. There are many illustrations, some from frozen sections of the cadaver previously hardened in formalin, and these are excellent.

The book is a large one and many of the sections are extensive, especially the one on the diseases of the bronchi, lungs, pleura and diaphragm. It is a valuable reference book, thoroughly revised.

WILLIAM E. MCCOLLOM.

at this level, together with low abdominal or rectal pain. Anemia and cachexia are late symptoms. A mass was palpable by rectal examination or through the abdominal wall in over 80 per cent of the cases, and proctoscopy usually showed the lesion. A majority of the lesions occurred in males (62 per cent). Roentgenographic examinations show filling defects with complete or incomplete obstruction. Lesions in the sigmoid, however, are easily overlooked by roentgenographic examinations, due to the fact that the bismuth-filled segments of the redundant sigmoid frequently fall down over the rectosigmoid junction.

Fig. 1.—Bismuth X-ray of a Carcinoma of the Transverse Colon. Note the typical hooking described by roentgenologists due to the sharp demarcation between the neoplastic and normal bowel wall and some degree of invagination at this point.

tion and so obscure the lesion. This is an important point to bear in mind and all experienced roentgenologists realize the necessity of manipulating the patient in various positions to visualize possible lesions at this level.

It is interesting to note that in a series of 100 consecutive carcinomata of the colon and rectum investigated by us to ascertain the frequency with which the textbook feature—alternating diarrhea and constipation—occurred, it was found present in but 8 per cent of the cases. I would like to stress the fact that this symptom, so often mentioned in

textbooks in connection with carcinoma of the colon, is a late symptom. It tends not to occur until some considerable degree of obstruction is present, and diagnoses should be made at an earlier stage before this has occurred.

The early diagnosis of carcinoma of the colon and rectum will not be made in an increasing number of cases until particularly middle-aged and elderly patients are educated to seek advice for any change in bowel function and until they are educated to readily submit to x-ray examination with bismuth enemata and to proctoscopic examinations. To make this possible, the costs of x-ray examinations by bismuth enemata must be brought down to such levels that they can be employed unhesitatingly upon doubtful cases. In addition to that, patients must be told and taught that there will be a great many negative findings. The price of early discovery of carcinoma of the colon is examination on suspicion and of necessity, because of the intangibility of early symptoms here, the suspicion will often prove groundless.

The need of adequate rectal examinations in suspected cases of carcinoma of the rectum is always stressed by those interested in this disease. That it needs repetition is evidenced by the fact that patients still come to us in advanced stages of the disease, never having had a rectal examination, although they have been under a physician's care for some time.

The casual rectal examination for a possible carcinoma, particularly of the rectosigmoid junction, will result in failure to discover it in many of these cases. When one attempts rectal examination for possible carcinoma of the rectum or low sigmoid, all possibilities of discovering the lesion digitally should be exhausted. The patients should be examined with one finger in the rectum and the other through the abdomen, bimanually. They should be examined in the squatting position, asking them to strain so that the sigmoid descends upon the examining finger, thus making it possible to discover high lesions which would otherwise be overlooked, and they should be examined in the knee-chest position on the examining table. When there is the slightest doubt, rectal examinations should be followed by sigmoidoscopic examination. Sigmoidoscopy is not a difficult thing to do; one readily acquires the technic, and many lesions that cannot be palpated can be diagnosed by this means.

In discussing carcinoma of the colon and rectum, one should have in mind that polypoid or polypoid masses in the colon are often forerunners of carcinoma. They are definite

precancerous lesions and should be dealt with with this in mind.

The incidence of polypi in the colon, as reported by J. H. Satint* is as follows: In 42 cases, 8 were in the cecum, 6 in the ascending colon, 3 in the transverse colon, 5 in the descending colon, and 20 in the sigmoid.

So prone are these polypoid masses in the colon and rectum to degenerate into carcinoma, that removal of the precancerous lesion is always justifiable. Unfortunately, they are often so numerous that an operative procedure for their removal, short of colectomy, is impossible.

The incidence of location of carcinoma, as already stated, in the 270 cases with which we have dealt, showed 75 per cent in the sigmoid and rectum. In another consecutive series of 100 cases, taken from our clinic records, the location was as follows:

TABLE II

12 per cent	were in the cecum
5 per cent	were in the ascending colon
3 per cent	were in the hepatic flexure
3 per cent	were in the transverse colon
1 per cent	were in the splenic flexure
7 per cent	were in the descending colon
15 per cent	were in the upper sigmoid
54 per cent	were in the rectum and rectosigmoid junction

The ages in this series of 100 cases were as follows:

TABLE III

1 case	occurred at 24 years of age
3 cases	occurred between 30 and 39
18 cases	occurred between 40 and 49
31 cases	occurred between 50 and 59
39 cases	occurred between 60 and 69
8 cases	occurred between 70 and 79

As has already been stated in discussing the symptomatology of these lesions, changes in bowel function must be a quite constant feature in connection with carcinoma of the colon. In this series of cases, constipation occurred in 56 per cent of all the cases, but in 65 per cent of those cases with carcinoma of the sigmoid. There was no disturbance in bowel function in only 9 per cent of the total number of cases. Twenty-seven per cent complained of diarrhea, half of these having carcinoma of the rectum, while but 8 per cent gave a history of alternating diarrhea and constipation.

The surgical treatment of carcinoma of the colon and rectum to accomplish any prospect of cure involves surgical procedures of major magnitude, such as abdominosacral removal of the entire rectum including the anus and lower sigmoid and extensive excisions of large segments of the colon for carcinoma located anywhere between the cecum and the rectosigmoid junction. There are several features about surgery of the large intestine which particularly tend to result in a high mortality

rate; many of the patients with this lesion are frequently advanced in years and poor surgical risks. They also frequently present themselves for surgical treatment with complete obstruction or some degree of obstruction. The character of the colon itself with its longitudinal bands, sacculations, and epiploic appendages, makes it a structure which lends itself poorly to an accurate suture line and anastomoses. In addition to this, as has already been stated, resections of the right side of the colon are made hazardous by the fact that the liquid contents of this side of the colon are easily disseminated and due to the virulent organisms harbored here, peritonitis readily results. Due to the even dry character at times of the fecal contents on this left side of the colon, solid masses of feces tend to lodge at the suture line where the colon is of necessity somewhat narrowed after resection, producing obstruction, distention, and danger of rupture and leakage at the suture line.

In removals of cancer of the rectum, the most desirable operative procedure is one such as the Miles operation, in which all of the rectum and sigmoid, including the anus, is removed at one time, together with the immediate establishment of a colostomy. Unfortunately, this procedure is so extensive that many patients weakened by the progress of the disease and with lowered resistance because of complete or incomplete intestinal obstruction cannot possibly endure such a radical procedure. The disadvantages of many of the two-stage abdominosacral operations for carcinoma of the rectum have been that they have involved complete division of the sigmoid above the level of the malignant lesion with complete loss of blood supply to the lower segment, an immediate colostomy being established and the lower segment of feces-filled sigmoid and rectum, unnourished by any nutrient vessel, being placed beneath the peritoneum in the pelvis to be removed at a later date. This results in necrosis of the lower segment, in dissemination of infected feces with pelvis, toxic absorption, and a marked intoxication of the patient.

We have modified this plan, as shown in Figs. 2, *a*, *b*, *c*, and *d* and 3, *a*, *b*, *c*, and *d* whereby a first-stage operation is done, establishing the colostomy, implanting the lower end of the cut sigmoid just above the pubis, ligating all of the vessels of its mesentery down to, but not including, the superior hemorrhoidal artery, and thus sustaining vascularization to the lower segment between the first and second operation. The wound is closed with a left ileac end colostomy through a counter incision and about the lower segment of sigmoid implanted just above the pu-

* Brit. J. Surg., 15, 1927.

bis, clamps being left upon both ends of the bowel as shown in Fig. 2, *d*. These clamps will slough off at the end of four to six days, by which time the wounds are sufficiently healed so that contamination does not occur.

At the end of six to seven days, an anal speculum can be introduced through the sphincter, an irrigating tube, as shown in Fig. 3, *a*, inserted in the upper end of the rectal segment, and this segment irrigated through and through two, three, or four times daily, this being repeated for ten to twelve days until the segment of rectum or sigmoid containing the malignant lesion is thoroughly cleansed. Two days before it is settled that the second-stage operation will be done, this segment is irrigated once or twice with mer-

curochrome to in some measure sterilize it. The second-stage operation is then done by closing the stump of sigmoid above the pubis (Fig. 3, *b* and *c*), by reopening the wound, ligation of the single nourishing vessel, the superior hemorrhoidal (Fig. 3, *d*), severing the parietal peritoneum above the rectum, separating it from the hollow of the sacrum, and pushing the rectal segment down into the pelvis. The pelvic peritoneum is then closed above this segment, the abdominal wound closed, the patient turned on his side, the coccyx removed, and the entire segment of rectum and anus removed from behind (Fig. 3, *d*).

The advantages of this operative procedure are: Between the first and second stage due

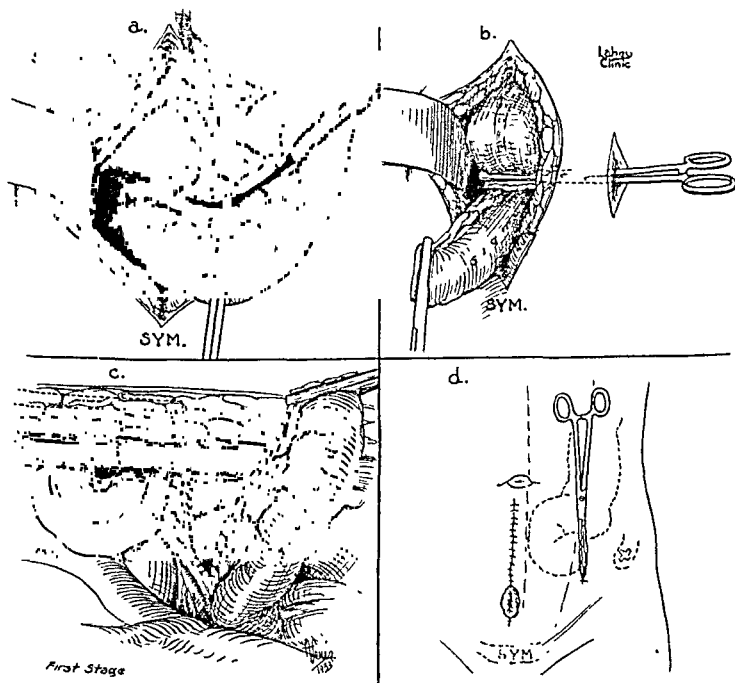

Figure 2

- (a) An incision has been made from the pubis to the umbilicus, the sigmoid pulled out and its mesentery ligated from the bowel down to, but not including, the superior hemorrhoidal artery.
 (b) A counter incision has been made to the left. An Ochsner clamp reaches through it and grasps the bowel. Another clamp grasps the bowel through the median incision and the bowel is cut between the two clamps with the cautery and the ends sterilized.
 (c) The upper segment of sigmoid has been drawn through the left colostomy incision to be the permanent colostomy. The lower segment is implanted in the median wound just above the pubis, the clamps remaining on both ends until they slough off.
 (d) The first stage completed. The left colostomy established and clamp still on the end of the sigmoid. The lower segment implanted in the median wound just above the pubis. The clamp not shown on this segment is likewise left on the end of bowel until it sloughs off.

to the fact that the lower segment of bowel is still vascularized, there is no urgency concerning the second part of the operation. One can delay as long as desired between the first and second stages until the bowels are moving well through the colostomy and until, with irrigation, the lower segments of rectum and sigmoid, as shown in Fig 3, *a*, are entirely clean.

One of the great advantages of this procedure in posterior removal of the rectal segment is lack of infection. The posterior wound in almost every instance heals by pri-

mary intention. Following other methods of removal of the rectum, contamination of the posterior wound not infrequently occurred, together with sloughing resulting in several weeks of discharge together with toxic absorption from the infected wound, a feature having definitely to do with mortality in these cases.

As evidence of the fact that carcinoma of the rectum has become a less serious operation in our hands, 29 consecutive radical operations for carcinoma of the rectum have now been done without a death. These opera-

Figure 3

- (a) Shows the vascularized rectal segment between the first and second stages of the operation and the method of cleansing this segment by irrigation between the first and second stages of the operation.
 (b) Beginning the second-stage removal. An incision made about the open end of the sigmoid implanted in the lower part of the median incision.
 (c) The open end of bowel closed as the first step in the second-stage removal of the segregated lower segment.
 (d) The median abdominal wound reopened, the superior hemorrhoidal artery and vein ligated and the incisions in the pelvic peritoneum represented by dotted lines around the rectum. The rectum is separated from the hollow of the sacrum and its pelvic attachments pushed down into the pelvis, the peritoneum closed over it and the abdominal wound closed.
 (e) The patient has been turned on her side, the coccyx removed and the rectum removed from behind.

tions, together with the colon resections, have all been done by Dr. H. M. Clute, Dr. R. B. Cattell, and myself. This mortality therefore does not represent that of a single individual. This operation, I believe, certainly in our hands, markedly diminishes the mortality for open operations in carcinoma of the rectum.

We have always felt that primary resection, either of the proximal or distal colon, was

fraught with serious danger due to the reasons already mentioned earlier in the discussion. We have always felt that when one resects a carcinoma of the ascending colon or of the descending colon, makes a primary anastomosis, and drops the sutured colon back into the abdomen, the die is cast and the patient lives or dies dependent entirely upon factors no longer under the surgeon's control.

Everyone who has been interested in the

Figure 4—Resection of the Colon by a Modified Mikulicz Plan

- (a) Demonstrates diagrammatically the method of resecting the right colon and the terminal ileum. Ochsner clamps are placed on the segment of colon to be resected above the growth shown as a shaded area in the illustration and on the ileum. The mesentery is shown cut away and the bowel is severed with a cautery between the clamps, and the ends sterilized.
- (b) Shows the ileum approximated to the transverse colon, both ends being held in the Ochsner clamps, thus preventing soiling.
- (c) Shows diagrammatically the anteroposterior suture of approximating the ileum to the transverse colon.
- (d) Shows diagrammatically the plan of staggering, which I proposed as a method of accomplishing immediate de-compression as part of this resection. Note that the mesentery to the ileum is ligated and a long section or staggered section of ileum is drawn out. The end of the transverse colon is shown in clamps, but for purposes of illustration, the clamp is not shown on the end of the ileum. A rubber covered clamp is shown to prevent escape of fecal contents and a glass tube is tied into it. The glass tube having been tied in the end of the ileum is connected with rubber tubing to a bottle at the side of the bed and immediate drainage in moderate degrees of obstruction can be accomplished locking it. This results in severing of the septum in four to five days and the partial establishment of the fecal stream. Because of the liquid contents of the ileum, a good deal of the ileal contents pass along the transverse colon. At this stage the patient is sent home for two months during which time edema disappears from the wound.

surgery of the large bowel must admit the dangers related to primary anastomoses at this location. It is difficult to do primary suture of the colon without some degree of contamination. Loss of blood supply to the cut edge of the colon is always a possibility. The colon is often so thin, particularly when any obstruction has been present, that satisfactory retention of sutures must always be in doubt. Even in the presence of preliminary cecostomy, one still must admit the dangers of leakage and contamination through primary sutures of large bowel, either with end-to-end or side-to-side anastomoses.

With the above view in mind, I published in *Surgery, Gynecology and Obstetrics*,* a

method of resecting the entire right colon and hepatic flexure by a modification of the Mikulicz plan of procedure, whereby the ileum could be approximated to the remnant of the transverse colon by the double-barrel plan, as practiced in the Mikulicz procedure, with later cutting of the spur and secondary closing of the resulting fistula some weeks after the primary excision of the growth.

This same modification of the Mikulicz plan, whereby a large segment of the bowel containing the growth, together with its adjacent mesentery is removed, clamps being left on the cut ends of the bowel, a double-barrelled spur being established, later cut and closed at a secondary operation, has proven of

Figure 5.—Second Stage of the Modified Mikulicz Removal

- (a) Shows the incision about the lumen of the artificial anus. This incision is carried through the skin, fascia, and muscle down to, but not through, the peritoneum.
 (b) The excision of the skin attached to the end of the artificial anus, refreshing the edges of the lumen.
 (c) The in, out, and over closure of the enterostomy opening inverting the edges of the bowel into its lumen.
 (d) A second row of inverting stitches closing the end of the lumen. Note that the peritoneum is not opened and that the entire closure is extraperitoneal and hence safe.
 (e) The method of carrying rubber dam down to the closed end of bowel and suture of the muscle over it.
 (f) Suture of fascia.
 (g) Suture of the skin.

There has been some leakage and contamination in a few of these cases but none have failed to close ultimately.

* Surg., Gyn. and Obst., 54:923-929, 1932.

marked value in our hands in carcinoma of the colon at all levels. In a series of 14 cases done in the last two years, but 2 patients (14.3 per cent) have died, one, an unavoidable death due to perforation of the lesion with abscess previous to operation, and the second a patient who succumbed to shock following this extensive procedure, due, I believe, since nothing was found at autopsy, largely to exhaustion as the result of an extremely large lesion and the length of time that the patient had had it.

The Mikulicz plan of procedure is applicable to any portion of the large bowel from the cecum to the rectosigmoid junction, except at the median portion of the transverse colon, and in some instances it can be applied here. In no case out of the series has the secondary fecal fistula failed to be successfully closed. This procedure has practically eliminated the danger of peritonitis in this operation, and, at the same time, it has permitted just as radical removals as does resection with immediate suture. It is infinitely safer in our hands than is the procedure of primary removal and primary suture.

The illustration of a plan of "staggering" which we have described with this operation, permitting immediate establishment of intestinal drainage in cases in which any degree of obstruction is present, is submitted (Fig. 4, d). This allows immediate decompression of a bowel distended from obstruction and is in our experience, a life-saving measure in connection with cases of this type. Figures

4, a, b, c, d, and e and 5 a, b, c, d, e, f, and g demonstrate the technical steps of the procedure.

OPERABILITY IN CARCINOMA OF THE LARGE INTESTINE—270 CASES

Inoperable patients (palliative)	122	45 per cent
Operable—radical resections	148	55 per cent

CARCINOMA OF LARGE INTESTINE—RESULTS FOUR YEARS AFTER OPERATION

Colon	47 per cent well (no recurrence)
Rectum	42 per cent well (no recurrence)
No patient has recurred after four years	

CONCLUSIONS

The symptoms and the operative dangers of carcinoma of the large intestine at different levels is discussed as relates to variation in function and anatomical structure.

Data as to location, percentage, age, mortality, and length of life after operation are submitted.

Patients should be urged that if they wish to discover carcinoma of the colon at an early and hopeful stage, attention must be paid to any abnormality in bowel function, that when such abnormality is present, bismuth enemata, and proctoscopy must be submitted to, and with the very distinct understanding that to diagnose one case early many negative findings must be expected. The reward of such a plan is a quite possible cure if a lesion is found and thankful mental relief if it is not.

Bill to Authorize Hospital Insurance.—A bill proposing to amend the state insurance laws to permit establishment of group payment plans of hospital care has been introduced in the state legislature. The measure is the outgrowth of a study made by the United Hospital Fund of New York, as a result of which a group plan was proposed to the state commissioner of insurance, who held that the existing law does not permit the establishment of such plans, and the present bill is designed to remove this obstacle.

S. 115 proposes to create a board of hairdressers and cosmetologists and to regulate the practice of hairdressing and cosmetology. S. 155 and A. 128, to amend the medical practice act, proposes to permit the board of regents to restore a license that has been forfeited, because of the commission of a felony, if the former licensee is pardoned by the governor of the state or by the President of the United States of the felony of which he was convicted. The present law does not permit the board to restore such a license if the person has been

convicted of a felony committed in his professional capacity. A. 77, to supplement the medical practice act, proposes to prohibit any physician or any other person or corporation from giving away, selling or offering to give away or sell any article bearing on it or annexed thereto any mark or symbol "pertaining in any way to the advertising of medical care or pertaining to any inducement of whatever nature respecting the furnishing or offering of medical care by means of such advertising." The bill proposes, too, to make it unlawful for any person or corporation, other than a duly licensed physician, to employ any person other than a licensed physician for the practice of medicine. The latter prohibition, however, is not to be construed to apply to the practice of medicine in the lawful operation of a hospital, dispensary, or other legally incorporated institutions. S. 45, A. 141 and A. 169, to amend the workmen's compensation act, propose, in effect, to make compensable all occupational diseases contracted in the course of an employment covered by the act.

SOME PRACTICAL CONSIDERATIONS IN PROCTOLOGY

By FRANK C. YEOMANS, M.D.
New York, N. Y.

Read at the Twenty-seventh Annual Meeting of the Sixth District Branch of the Medical Society of the State of New York, Norwich, N. Y., October 18th, 1933.

The field of proctology comprises the colon, especially its distal portion; the rectum, and the anal canal. Due to improved methods of examination together with laboratory aids, the diagnosis and treatment of diseases of this formerly obscure area have now attained a high degree of accuracy. This presentation will cover briefly some points of general interest which, I trust, may be of practical value.

PILONIDAL SINUS (SACROCOCCYCEAL CYST).—This is a congenital anomaly situated over the sacrum and is due to failure of even fusion of the ectoderm in this part of the midline. It is evidenced by a dimpling in about 30 per cent of young infants. In the majority of cases the depression is obliterated as the child develops, but in a few it persists. In some of the latter it causes no symptoms while in others pathologic changes occur. The latter group comprises mostly husky young men, from 18 to 35 years of age, who are hirsute. Thickening of the panniculus deepens the sinus, thus forming a human culture tube at constant body temperature, lined with skin, and receiving the secretion of sweat glands and hair follicles, and containing myriads of bacteria and irritating hair. Inflammation and discharge of pus ensue, for which relief is sought. Quite commonly a diagnosis of abscess or fistula is made, and treatment by incision and drainage is followed by prompt relief. Unfortunately this does not end the trouble permanently. Usually within about six months there is a recurrence and temporary relief by the same means, unless close inspection is made. The examiner will then find over the lower sacrum an indurated and usually inflamed swelling, and precisely in the midline he will see from two to five openings, some minute, others larger and fistulous, through which bristly hairs may emerge, and discharge oozes or can be expressed. Naturally, recurrence followed simple incision for we are dealing with a cyst.

The only effective treatment is to excise en masse, under local or low spinal anesthesia, the entire area involved by an elliptical skin incision, deepened in wedge-like fashion to the sacral fascia. The wound heals by granula-

tion, but occasionally cases, in which infection has been reduced to a minimum by drainage, may be sutured and primary union obtained.

A majority of the cases in my practice had been operated upon from one to four times with the erroneous diagnosis of abscess or fistula.

PRURITUS ANI.—This is a most tantalizing and distressing ailment which may lead to neurasthenia and other neuroses. True pruritus ani is a definite dermatitis of the perianal skin due to infection. The chief offending organisms are *B. coli* and streptococci which gain entrance directly or through anal ulcers, sinuses, or crypts. Clinically it occurs in the moist and the dry forms. It must be differentiated from trichophyton infection and various dermatoses. Many of the latter are due to neglect of local hygiene or are secondary to pathologic states of the anus and rectum.

Appropriate surgical treatment of infected crypts of Morgagni, hypertrophied anal papillae, chronic fissures and ulcers of the anal canal, and prolapsing ulcerated hemorrhoids will frequently eliminate the trouble. True pruritus must be carefully differentiated from these cases. For example, the removal of simple internal hemorrhoids may aggravate the itching of a complicating genuine pruritus ani.

Appropriate diet and cleanliness are important in the therapy. Suitable local treatment of the involved skin taxes the ingenuity of the clinician and the patience of the sufferer. The subcutaneous injection of an anesthetic in oil frequently relieves the itch promptly and is often curative. One of the best of these is benacol. Due to its possible attendant dangers, treatment by the x-ray is contra-indicated.

COCYGDYNIA.—The pain in coccygodynia is usually referred by the patient to the rectum. Without careful local examination its true nature may be missed. It most commonly follows trauma, as parturition or a fall. After fissure, infected crypts of Morgagni and other painful lesions of the anal canal have been eliminated by examination as the causative factor, the index finger is inserted into the rectum and counter-pressure is made by the thumb of the same hand externally. Thus

one can determine the position and contour of the coccyx, its possible dislocation, and normalcy or ankylosis of the sacrococcygeal joint.

Next, the soft tissues at the tip and sides of the coccyx are compressed. If the exquisite and characteristic pain, like that of which the patient complained, is produced it is a case of coccygodinia *ie* a neuralgia or neuritis of the coccygeal plexus of nerves.

Formerly it was considered good practice to remove the coccyx at once to obtain relief. In some cases the pain persisted after the operation.

Several years ago, conceiving the trouble to be in the nerves and not in the bone, I began to inject 70 per cent alcohol into the painful area, after the method of Schlösser in trifacial neuralgia, with most happy results. In the majority of cases, from three to five injections gave complete and permanent relief. In any case, even of fracture or dislocation of the coccyx, or ankylosis of the sacrococcygeal joint, unless the tip of the bone points backward, the injections, which are harmless and easily given in the office, should be tried before resorting to excision.

If the injections fail, excision of the coccyx is usually successful, not primarily on account of the removal of the bone but chiefly because the plexus of nerves is severed or excised at the same time.

ABCESS—In its onset a painful, tender, in duration, the result of external or internal infection, may occur at any point about the anus. Should this early induration be incised at once? No. I think not. First, antiphlogistics should be applied until a definite point of fluctuation can be determined. Then the abscess should be opened widely, *ie*, the skin incision should be as long as the broadest part of the abscess. The stab puncture so frequently done obstructs free drainage, and suppuration is prolonged. After the first packing, drainage should be very light and healing prompt.

If discharge persists from the sinus of a nontuberculous abscess correctly treated, a complete fistula has most probably developed which is continuously infected through a portal of entry in the mucosa usually situated between the sphincters. Cure will not be obtained until the fistula is incised its entire length or the tract excised.

Due to tortuosity of the fistulous tract, a probe may not pass through its pathological internal opening. The latter may be simply and painlessly demonstrated by injecting an indigo dye in peroxide of hydrogen solution through the external opening.

In the event that a complete fistula was present and discovered when the abscess was opened, the rule of first draining the abscess is correct, in order to reduce the active infection before treatment of the fistula. Much less surgery is thus required and sound tissues are not exposed to the virulent infection.

Abscesses sometimes occur in suckling babes and frequently fistula results. The abscess should be drained at once and after the active infection has subsided the fistulous tract may be excised intact and the wound closed by suture. In the actively growing tissues of infants primary union may be expected quite in contrast to the chronically infected tissues of adults.

Occasionally the question arises of opening an abscess which may or may not, be tuberculous, in a patient having pulmonary tuberculosis. Tuberculous abscesses, especially if secondarily infected markedly aggravate the lung condition, yet many physicians oppose surgical intervention because they either have had cases in their own practice so treated or have heard of them in the practice of others which within a few months after the operation, developed general military tuberculosis to which the patients succumbed. This is recorded in the older textbooks and was true when originally penned, but it is not true to-day. What makes the difference? It is the technique of the operation. In all cases suspected of being tuberculous the patient receives a small dose of low spinal or gas oxygen anesthetic and the incisions are made with the electric cautery. The eschar resulting seals the lymphatics and protects the wound margins until granulations—nature's own protection—form and bar general dissemination of the infection. The relief to the patient both local and general, is surprisingly great.

Pain and bleeding are the two most urgent symptoms that bring the proctologic patient to the doctor.

FISURE OF THE ANUS—The exquisite pain of fissure is out of all proportion to the size of the lesion. Local irritation of the fissure usually causes spasm of the sphincter muscles aggravates constipation—the commonest primary cause of the fissure—and may finally lead to intestinal toxemia and its sequelae. Local infection through the fissure may result in abscess and fistula. Irritation of the nerve terminals exposed in the fissure may reflexly cause symptoms simulating cystitis, dysmenorrhea, lumbago, sciatica and various neuroses. Consequently a fissure should be treated promptly.

The first essential is to obtain a duly boweled action by properly regulated diet and mild

laxatives, not drastic cathartics. The mistake is frequently made of tying up the bowels. This gives only a false sense of relief for when a movement finally occurs the scybala are apt to reopen the fissure.

If seen within a few days of its occurrence, an acute fissure can usually be headed by injecting a local anesthetic beneath it and into the adjacent external sphincter muscle. Quinine and urea hydrochloride in 5 per cent solution and benacol are the types of anesthetic used to produce prolonged analgesia and relaxation of the sphincters. As soon as the anesthetic has taken effect the sphincter muscles are gently dilated and pure ichthylol is applied to the lesion.

When dealing with a recent painful lesion of the anus, the question of a primary chancre may arise and is to be decided at once by finding *Spirochitae pallidae* in the dark-field examination of secretion expressed from the sore.

A chronic fissure, the familiar "irritable ulcer" with muscle spasm, is best treated by dissection out of the scar tissue under local anesthesia and superficial division of the external sphincter through the usual site of the lesion, namely, posteriorly, but sometimes in the anterior commissure in women. This procedure always cures; therefore, it is more reliable than division of the anal canal under general anesthesia.

A chronic fissure must be differentiated from an epithelioma which is very painful and exquisitely tender, and infiltrates adjacent tissues in a characteristic manner. Three cases of epithelioma which were being treated under the erroneous diagnosis of chronic fissure have occurred in my practice.

HEMORRHAGE.—Bleeding from the rectum is such an important symptom that we have not rendered full service to the patient until its source is determined, if possible. The commonest sources of massive hemorrhage, in my experience, have been malignant disease, usually of the rectum; rupture of sclerotic varices of the mucosa in the elderly, rupture of a hemorrhoidal vein, erosion of a blood vessel in chronic ulcerative colitis and, in adolescents, bleeding from an ulcerated Meckel's diverticulum.

Sudden, massive hemorrhage from the intestine often gives rise to alarming symptoms. As a rule, surgical intervention is not urgent. It may end in disaster and the source of the hemorrhage remain undiscovered at operation unless it was determined in advance of the abdominal exploration. With palliative treatment, aided by the fall of blood pressure which naturally accompanies the bleeding and favors coagulation, usually the active hemor-

rhage is checked spontaneously. A later study under more favorable conditions is more likely to disclose the source of the bleeding and dictate the correct procedure to prevent its recurrence.

The commonest source of rectal bleeding is internal hemorrhoids. Periodic blood loss from hemorrhoids in the plethoric may be salutary, but regular, daily bleeding frequently causes severe secondary anemia and its consequences. Several of my case records show a hemoglobin percentage of 30 or less and in some instances the diagnosis had been pernicious anemia or cancer of the gastro-intestinal tract.

The diagnosis of bleeding from internal hemorrhoids may present difficulties. Generally, with the cooperation of the patient, the tumors can be protruded and seen. Exceptions are a tight sphincter in nervous persons, and muscle spasm due to fissure. Hemorrhoids, unless thrombosed or inflamed are not painful. Notable pain is usually due to a complicating fissure.

How may we recognize active internal hemorrhoids that can not be extruded? Digital examination is practically negative except when the vessels are inflamed or thrombosed, or after chronic fibrous changes have occurred. In the latter, prolapse and not bleeding is the dominant complaint. The most reliable method of diagnosis of concealed internal hemorrhoids is their inspection through an anoscope. If a complicating fissure is present, topical application of 4 per cent solution of cocaine will obtund the pain during the examination.

Hemorrhoidectomy under local anesthesia is the best procedure for permanent results; but when operation is contra-indicated, as in pregnancy, old age or constitutional conditions, such as diabetes and tuberculosis, the injection method gives very satisfactory palliation in uncomplicated internal hemorrhoids.

Even if actively bleeding internal hemorrhoids have been demonstrated, the examination does not end there for piles may be, and too frequently are, associated with, or secondary to, more serious pathologic conditions at a higher level, notably cancer and stricture. It is conservatively estimated that 15 per cent of patients having cancer of the rectum are treated palliatively or operated upon for "bleeding piles" when the neoplasm is within reach of the examining finger or the proctoscope. The practical conclusion is that no patient who has bleeding internal hemorrhoids should undergo treatment until a digital examination and proctosigmoidoscopy have been done.

Medical literature records an increasing

number of cases of hemorrhage especially in children and adolescents, traceable to an ulcerated Meckel's diverticulum. The bleeding may be periodic, of rather large volume and its source obscure. Unfortunately roentgen study does not demonstrate a Meckel's diverticulum, so celiotomy is justified in these cases of obscure hemorrhage after routine measures of diagnosis have failed. Needless to say, the terminal three feet of ileum should be examined for a possible diverticulum in the course of any abdominal exploration.

Bleeding in children is usually attributed by the parents to prolapsing hemorrhoids. In fact, children seldom develop hemorrhoids before puberty. What the mother really sees is a partial or complete prolapse of the rectum, or a rectal polyp which may be felt by the finger or discovered by the proctoscope.

Another and rarer source of bleeding, seldom suspected, occurs in constipated children and is due to invagination of the sigmoid into the rectum. Congestion and ulceration may ensue, with the passage of fresh blood with the stool. This condition can be recognized only by instrumental examination and corrected by restoring normal physiology of bowel function.

DIGITAL EXAMINATION.—The experienced finger not only feels anything within the bowel lumen but also palpates lesions of the terminal $4\frac{1}{2}$ in. of the rectum proper, such as a mural abscess, indurated ulcers, stricture and tumors; and pathologic changes in adjacent organs, as the prostate and seminal vesicles, and displacements, as a retroverted uterus.

A point of diagnostic import is careful palpation of the rectovesical culdesac. This examination should never be omitted in cases of suspected acute appendicitis in men. Certain chronic conditions may also manifest themselves here. This refers particularly to implantation carcinoma in which cancer cells, detached from a tumor situated at a higher level within the peritoneal cavity, gravitate to the culdesac, engrafting themselves on the peritoneum, and produce a palpable induration, described by Blumer as a "rectal shelf." When this is felt per rectum, the primary tumor has metastasized and is radically inoperable.

Plastic tuberculous peritonitis may, to palpation, mimic carcinoma in the culdesac. However, it is less indurated and is to be differentiated by the history, symptoms, and other physical signs.

Examination of a parous woman is completed by a vaginal examination.

PROCTOSIGMOIDOSCOPY.—How about lesions beyond reach of palpation? Here the modern

pneumo-electric sigmoidoscope is indispensable, serving as an elongated finger with a human eye. By it one can readily inspect directly the entire rectum and, in about 75 per cent of cases, the distal loop of the pelvic colon. The condition of the mucosa is clearly seen as normal, atrophic, or hypertrophic; and various types of ulceration may be recognized, such as tuberculous, hemorrhagic, chronic nonspecific, and amebic. Material is taken directly for smears, cultures, and the making of autogenous vaccines.

In its early stages amebic dysentery presents a pathognomonic picture and the diagnosis can be confirmed at once by finding on the warm stage of a microscope motile *Amebae histolyticae* in the scrapings from the characteristic, discrete, pearl-like, necrotic ulcers.

During the past 35 years intercourse with the tropics has so increased that amebiasis is comparatively common in the North. Frequently carriers of the infection go from one physician to another and from clinic to clinic without a correct diagnosis because of lack of competent examination. However, not all of these cases are imported, many being native; therefore it does not necessarily follow that a patient with amebiasis give a history of residence in the tropics.

From an experience in approximately 125 cases of amebic infection, I would emphasize the gratifying results when thorough treatment with emetine hydrochloride and stovarsol is instituted sufficiently early, that is, before the specific ulcers have become secondarily infected with the usual intestinal flora. Then the specific remedies alone are without avail and additional measures, appropriate for the treatment of nonspecific chronic ulcerative colitis, must be employed.

STRICTURE AND TUMORS.—A stricture or tumor is clearly seen through the proctoscope, and a graduated tube of small caliber can usually be passed through the lumen of a stricture or beyond a tumor to the normal mucosa above, thus determining the length of the process.

Biopsy.—In all cases of doubtful diagnosis it is my practice to do a biopsy with the harmless high-voltage electric snare and so to remove uncertainty at once. The alleged danger of possible dissemination of cancer cells by a properly performed biopsy is minimal in comparison with the positive information obtained. Major values of the biopsy are: (1) differential clinical diagnosis, (2) prognosis, and (3) to indicate therapy. In the case of a very small tumor, the entire lesion should be removed for study. I know of three cases, at least, in which the rectum was excised without previous biopsy of the ulcerous lesion and careful

histologic study of the specimens demonstrated only chronic inflammation. Fortunately, all three patients recovered from the operation.

The bleeding from a solitary polyp is promptly ended by its removal by ligature or fulguration when it is situated low in the rectum, or when at a higher level, by fulguration or the electric snare passed through the proctoscope. If proctoscopy reveals a condition of multiple polyposis, in which myriads of small, usually adenomatous tumors are commonly scattered throughout the colon, local excision is futile. No measure short of ileostomy or cecostomy efficiently diverts the continuous infection which stimulates the growths. Should the tumors not recede or disappear after enterostomy, excision of the involved bowel is the only hope of cure. If neglected, over 40 per cent of cases degenerate into carcinoma.

All specimens of tissue removed at operation or otherwise should be studied histologically.

Because of the protean manifestations of syphilis, a Wassermann test of the blood should be made in every case of ulcer, stricture, or tumor of the rectum or colon.

Urinalysis should be routine in all cases. Glycosuria or a high blood sugar has explained a number of cases of pruritus and of progressive weight loss. In some of the latter, malignant disease of the gastro-intestinal tract was suspected.

Roentgen Ray Examination.—When the patient has symptoms referable to the distal bowel or bleeding is present, frequently the first thought is an x-ray study of the gastro-intestinal tract. This is putting the cart before the horse. The rays usually fail to demonstrate lesions of the lower pelvic colon and rectum, such as ulcers, small polyps and adenomas, and early cancer. In fact, the false sense of security engendered by a negative roentgen report may so delay correct diagnosis that the time for hopeful therapy may be lost.

The other methods outlined above establish the diagnosis in the vast majority of diseases of the rectum and pelvic colon and, in my experience, they should be first applied. With these data on hand, the roentgenologist is in a position to study his patient with a high degree of intelligence.

555 PARK AVENUE

CHISELLING THE POOR

In every relief program are found three types of beneficiaries. There is the professional type, made up of the chronic "down-and-outers," derelicts of society who are floating rudderless in the sea of human endeavor without hope or expectation of regaining anything like their proper places in the social fabric. These people constitute the nucleus around which organized relief is found, wherever people congregate anywhere on the face of the earth. They have existed since time immemorial and they are as much a fixed part of the earth's population as is the usual productive majority. Quick to complain, difficult to satisfy and hard to control, they constitute a knotty problem which sociologists, psychologists, and political economists have long sought to solve and remedy, without evidence of success. We must, therefore, accept them as a fixed responsibility at least for the present and we are not now concerned with anything more than recognizing their existence and fulfilling our duty to them as fellow humans.

The second type is derived from the unfortunate people who have, especially in stressful times like these, temporarily at least, reached the end of their resources and are forced to seek relief. They are properly entitled to the consideration that humane impulse dictates and for them the resources derived from taxation and other sources of public revenue, as well as those resulting from private benevolences are provided and administered, always with the thought of maintaining the self-respect and preserving the potential earning powers of these people who have been caught in the maelstrom of economic stress, often through no fault of their own.

The third type represents a curious development of modern trend, the people who have some financial means but who, selfishly try to take advantage of the resources which have

been provided for their less fortunate fellows. It is safe to assume that this class has been fostered and encouraged in its development by the efforts of our friends the sociologists in their desire to gloss over the stigma which is supposed to be attached to the receipt of public assistance. This sociological influence has extended much further than the field of public relief, so that we find it operative in the conduct of penal affairs as well. Our present system of conducting prisons and workhouses is apparently based on the reformatory idea, praiseworthy enough in theory, but clearly not applicable without individual classification. In order to save the first offender, the professional criminal is included in the program, so that prison life is made almost attractive. The real victims are their unoffending families.

But let us return to relief proper; and this now includes not merely the furnishing of food, shelter, heat, and clothing, but hospital, dispensary, home treatment, and nursing. The point we are trying to make is, that all these forms of assistance belong purely and solely to the first two types of beneficiary and not the third. This last, the chiseler, can be fairly easily stopped in the food lines, but it has been found increasingly difficult to keep him out of the free beds. Every bed so occupied keeps out a worthy applicant and is being paid for by funds never intended for that purpose.

The medical profession now tardily awakes to the gravity of the situation and is making concerted efforts to find a remedy. It should be encouraged and supported by all right-thinking people. Public opinion is being aroused. The taxpayer is becoming interested. But the true sufferers are the worthy poor, who are being cheated out of the facilities and relief which have been provided by a humane public.

TUBERCULOUS PULMONARY CAVITIES

By EDGAR MAYLER, M.D.
Saranac Lake, N. Y.

Read before the Section on Medicine at the Annual Meeting of the Medical Society of the State of New York at New York City April 4, 1933

The depressing statistics on the outlook of cavities in the tuberculous that have been reported in the past stimulated our own studies along these lines. Many workers have reported that the majority of such patients have died within five years.

On closer analysis it has been found that this depressing outlook depended more upon the extent and nature of the surrounding and accompanying pulmonary tuberculosis than upon the cavity itself. Thus the outlook for the far advanced disease has always been recognized as serious regardless of cavity.

On the favorable side, according to our own studies, we are able to emphasize that cavities detected in their earlier period of formation, cavities which have been designated by such terms as "round" or "elastic" or young, have a most favorable outlook with an enforced strict bed rest. Thus of 39 such cavities, 21 have disappeared in five months, and 8 have become much smaller, from their original size of about 3 cm in diameter. Cavities of both young and older formation can disappear in about 40 per cent of the patients on enforced strict bed rest of from one to two years, especially if their closure is not interfered with by the nature or extent of the surrounding disease. About 60 per cent of patients with cavity are still living at the end of five years. The patient with small cavity will survive twice as often as the one with large cavity, about twice as often if the surrounding disease is minimal, than if it is moderately advanced, but seven times as often than if it is far advanced. Our own figures of over 200 cases as well as a much larger series from Trudeau Sanatorium which will be shortly published by Mr. Homer Sampson, and those of Faules and Beaudet, etc., reveal this.

Our own knowledge of the development of cavities emphasizes that the time factor for interfering early should be stressed. These cavities develop rapidly from tuberculous bronchopneumonia, especially in the region below the clavicle, although they may be seen anywhere. The stages of development from infiltration to caseation with final sloughing, the development from the young cavity to the old rigid type can be easily recognized. There are indeed other forms developing as

multilocular formations in dense areas of caseous pneumonia bronchiectatic cavities, and those with narrow anteroposterior diameters, which should be recognized.

It is not the cavity itself that decides the outlook so much as many related factors. These include the age size and number of cavities, their location in relation to the center or the periphery of the lung, their positions in the upper or lower lobe, especially as concerns their drainage and their proximity to the pleura, both parietal and interlobar. Small cavities are more prone to heal. Cavities in the aged are consistent with longer life than those in the young. Central cavities are more liable to heal by concentric contraction, while the peripheral cavities are likely to form pleural adhesions early and should therefore be collapsed sooner.

Brandlike and fingerlike pleural adhesions are found much more often in the upper lobe region, to the extent of almost 90 per cent, especially dorsolaterally. Almost 40 per cent are found between the second and fourth rib and around the midaxillary line. Not many less are found in the same region but nearer the spine. They are commonly found along the slant of the interlobar fissure in the upper lobe region.

Most cavities are also found in that region, from 60 to 70 per cent being in the region of the subapical bronchus and apical bronchus. About 90 per cent of the cavities are located dorsally. If nearer to the base, then the cavity is more likely to be found toward the anterior part of the lung.

The aims of treatment should be to close cavities and to obtain negative sputum. Persisting cavities constantly secreting tubercle bacilli are very likely to induce hemorrhage or spread disease by aspiration and extension or induce amyloid disease.

The aim of treatment of cavities by measures of interference should be to appose the walls, perhaps close the draining bronchus, enforce pulmonary rest and relieve pull on cavity, if not to directly compress it. Most of this depends upon the surrounding disease rather than upon the cavity. Treatment of the young cavities should aim if possible at prevention of pleural adhesions and forestall formation of rigid cavity. Sometimes dense surrounding disease is often the factor in interference with closure of the cavity by

such attempted measures as pneumothorax or operations on the phrenic nerve.

Cavities heal often by apposition with formation of dense pleural thickening or they repair by fibrosis, shrinkage, and obstruction, which may be aided by atelectasis. More rarely do they heal by encystment and calcification.

In treatment of early cavity, especially beneath the clavicle, serial x-ray and careful clinical watching is most essential during the first few weeks. With evidence of increas-

ing disease or enlargement of cavity, immediate collapse is indicated.

Operation on the phrenic nerve will, as a rule, close completely only the young cavities with little surrounding disease. The older cavities with more disease are usually diminished in size but rarely close by this measure.

The more radical therapy such as thoracoplastics, pneumolyses, etc., is indicated, for older cavities with more extensive disease, generally adherent, especially so with giant cavities of the upper lobe.

SOFT-TISSUE RADIOGRAPHY

By JOHN R. CARTY, M.D.

Radiologist to the New York Hospital, New York, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 5, 1933.

The average radiographic study of an extremity usually consists of an adequate investigation of bone detail, the roentgenologist often contenting himself with a bare outline of the soft tissues. In most instances the soft-part anatomy is given little consideration. Studies are rarely made, for example, to show the extent and nature of nonosseous tumors. Roentgenography of the soft tissues is an interesting type of work which greatly enlarges the scope and value of an x-ray examination. It deserves more attention on the part of the roentgenologist. The slight extra effort required should not be an excuse for overlooking its possibilities.

For various reasons, such as slight technical difficulties and lack of appreciation, we as roentgenologists have neglected this field. For a satisfactory study one must not be content with bare outline but should demand the same detail within these structures as is required of bones. A thorough knowledge of the anatomy of the soft parts, particularly their relation to the osseous structures, is required for the best results.

We will discuss briefly what can be expected from an adequate x-ray study of the soft tissues: Visualization of normal arteries and veins, particularly at the flexures, can be obtained. Deep varicose veins, especially those in the lower extremities, can be demonstrated. This is a diagnostic aid particularly if there is no evidence of superficial involvement. It may determine whether the injection treatment should be given. Early calcification in the arteries becomes apparent with

the proper technic, usually sooner than heretofore. About the knee, the popliteal nerve and its branches can often be shown. In a recent gunshot case we were able to demonstrate several buckshot in close relation to the external popliteal nerve, thus materially aiding the surgeon. The presence and extent of blood vessel tumors can often be well shown. They have a characteristic, mottled, worm-like appearance. It is sometimes possible to say whether or not the tumor has broken through a capsule, if present.

The extent and nature of tumor masses involving the muscle can also be demonstrated. Early calcification in hemorrhagic exudate becomes visible. Extravasation of body fluids or blood in the muscles gives rise to a smooth obliteration of muscle detail, which permits recognition of this condition. If circumstances are favorable, a ruptured muscle may sometimes be seen.

Subcutaneous structures offer an excellent field for soft tissue investigation. In cases of suspected elephantiasis, considerable information can be obtained.

While necessarily the solid-bone detail is not satisfactory, various early periosteal changes are well shown. Similarly this method forms an excellent means to study the growth of callus. The same principles can be applied to abdominal work with equally good results. Gallbladder shadows, even though containing a relatively small amount of dye, are made denser and more distinct. Kidney outlines become sharper. Liver and spleen outlines are very distinct, thus minimizing the necessity for possibly hazardous methods which utilize intravenous injection

of radioactive materials. Encapsulated abdominal masses appear quite distinct. Fetal structures become visible earlier during pregnancy. In women before menopause the uterus and bladder can often be outlined, tumors and displacements shown. In this, as in all abdominal work, extra care must be taken in the preparation of the intestines. Gas and intestinal contents will obscure the various organs, even with the most careful technic. The bladder preferably should be empty before radiography.

In the chest there is marked improvement in the delineation of heart and lung structures, provided there is sufficient milliamperage available to make the exposure rapidly.

There are several vital factors in the technic which should be considered; perhaps the most important being the relation between the number of milliamperes-seconds and the K.V.P. voltage used. Warren has stressed the necessity for a high milliamperes-second ratio and as low a voltage as is consistent with adequate penetration of the part. In our experience with the present x-ray tube limitation, 250 to 300 milliamperes-seconds is most satisfactory to use for abdominal and extremity work. By this simple expedient alone the diagnostic value of the radiograph greatly increased. This is due, in a large part, to the increased contrast caused by the lowering of the voltage. In addition to the sparkle of the lower voltage radiograph there is an actual increase in sharpness of outline, entirely independent of motion. This factor is very important in the final result and is often overlooked.

In order to bring soft tissue radiography within a practical realm the machine must have good regulation; otherwise it is difficult to duplicate results. It is imperative that the autotransformer should not have steps larger than 2.5 K.V.P. A steady line is necessary as fluctuation will cause irregular results. While the high milliamperes-second ratio introduces an element of danger to the skin, due care will avoid trouble. Until the technic is established, trial exposures are advisable.

The x-ray tube should have as small a focal spot as is consistent with keeping the time of exposure within reasonable bounds and not

overloading the tube. This adds to the wealth of detail and permits of visualization the fine, delicate fascial planes in the subcutaneous structures.

The film employed must have a clean base and be as free as possible from inherent fog. A contrast emulsion gives the best results. Practically all of the film manufacturers are now striving to make this type of film. Development should be by the sight method. This requires some experience. The time and temperature technic is not at all suited for this work, which should be treated as a specialty. At the New York Hospital a separate, small darkroom has been installed to take care of this class of radiography. We have thus been able to do consistent soft tissue radiography in a large department. Fog of any kind is ruinous to results. Care should be exercised in the process of developing so that chemical fog is not formed. Double screens may be employed, although single ones give better results due to the lack of absorption of the extremely soft radiation by the screen.

If it is desired to obtain both bone detail and soft tissues at the same time, card board holders are used. The combination film, however, sacrifices some soft tissues and bone quality. If film holders are used they should be well backed with lead to prevent secondary fogging.

The technic is extremely selective. As stated before, it is sometimes necessary to make a test exposure with a small film. If it is desired to visualize vessels, slightly higher penetration will be necessary in muscular individuals than if the subcutaneous region or muscles are under investigation. Exposures in various positions may be necessary to avoid overlapping of bone detail. Too extensive an area should not be attempted on one exposure because of the exact penetration needed for a given part.

CONCLUSION

Soft-tissue radiography offers a valuable field of investigation for the roentgenologist, greatly increasing his scope of diagnosis. The various conditions suitable for soft-tissue study are discussed. Essential points of technic are emphasized. A plea is made for more interest in this field.

1300 YORK AVE.

Dr. Wynne Accepts Position with Milk Institute.—Dr. Shirley W. Wynne, formerly health commissioner, has accepted the presidency of the Greater New York-New Jersey Milk Institute, an organization of milk dealers in the metropolitan area, according to the

New York Times. Dr. Wynne's duties will be largely educational among producers, dealers, and consumers, and he will represent the institute at hearings of the State Milk Control Board. The announcement stated that Dr. Wynne will also engage in medical practice.

THE RELATION OF UPPER RESPIRATORY INFECTION TO NUTRITION IN INFANTS AND CHILDREN

By MARSHALL CARLETON PEASE, M. D.

*From The Service of the Babies Wards
New York Post Graduate Medical School and Hospital,
New York, N. Y.*

Read before the Pediatric Section at the annual meeting of the Medical Society of the State of New York, April 4, 1933.

In considering the relation of infections to nutrition in infants and young children I realize that I am taking up a controversial subject. However, it is possible to arrive on nearly common grounds if it is accepted at the start that not all infants and young children who are suffering from nutritional disturbances are suffering from a focus of infection. Three basic factors explain much of the present infant mortality rate: the first is improper feeding, the second is true enteric infection restricted to the gastro-intestinal tract, and the third is a parental infection characterized by a focus outside of the gastro-intestinal tract.

The first two of these factors are well understood and are on the whole adequately cared for. As to the third point, all physicians accept the clinical association between parental infection and intestinal disturbance, though many have not accepted the hypothesis that a large number of cases of gastro-enteritis are caused by middle-ear or sinus infections. This last proposition has, however, been ably supported by numerous pediatricians and otolaryngologists¹⁻⁵. Paranasal sinusitis has been shown to be of considerable frequency in children⁷⁻¹⁰. It is my own conviction that it is difficult to exaggerate the importance of these infections from the standpoint of either immediate or remote effects, and that they may be the underlying cause of such divergent groups of symptoms as characterize gastro-enteritis, bronchopneumonia, and nephrosis.

There are obvious infections in children which are not compatible with life or good health and which are nevertheless so chronic in their progress that striking changes in nutrition take place. Conditions of this nature may occasionally clear up, leaving behind a permanently damaged individual in so far as nutrition and growth are concerned.

There is another less easily recognized group of cases which are classified as upper respiratory infection. Apparently we must revise our conceptions of what an acute cold is. An acute cold involves not only the nasal and nasopharyngeal mucosa but the lining mem-

brane of the sinuses as well. The duration and the number of attacks an individual must have before there is evidence of a chronic change in the membranous lining of the sinus itself or in the bone depends upon individual variation, which in turn may depend upon age, susceptibility, and virulence of infection.

Almost any of the pathogenic organisms are found in these cases of parental infections and sometimes several of them are associated, but the streptococcus group is the one most frequently isolated.

Age is of some importance. In a study of our cases almost half the deaths in the entire group occurred during the first five months, and one-fourth of them in the first two months. This is partly explained on the ground that the very young have not yet developed the immunity which they will have to disease at a later period in life and that many of the disturbances which are so severe in these early months are in reality a part of the process of developing immunity. Certainly, they rarely suffer from a septicemia, and older children may survive a serious and prolonged upper respiratory infection without loss in weight or physical discomfort. As children grow older, profound disturbances of nutrition tend to become less noticeable and the complaints are more generalized, such as nasal discharge, epistaxis, repeated colds, cervical adenitis, occult and recurring fever, irritability, lack of progress in school, depression, loss of memory, and hypersensitiveness.

The suggestion that enteritis in children is due to an inflammatory process in the middle ear and mastoid alone is incorrect. Thereby we do not mean to state that absorption may not take place from the ear and mastoid, but we have proven, at least to our own satisfaction, that the primary infection in the majority of cases is in the nasal passage and sinuses.

The nose, throat, and ears of a one-half-month-old baby are difficult to see clearly. A slight reddening of the throat is often partially concealed by a thin gray membrane. The mucosa lining the nose in the earlier stages of a cold is swollen, red, and dry, and it may be two or three days or longer before a running nose develops; and even then the dis-

charge may be entirely postnasal. The nearly normal appearing ear drum has a significance which is not infrequently overlooked by the otologist and pediatrician. It is not widely appreciated that the ear drum may appear nearly normal, though with an acute mastoiditis behind it, the history is not negative if carefully taken. In a study of our cases operated for a diseased mastoid the drum appeared normal once or twice in 73 operations. We are of the opinion that a practically normal drum will cover a diseased mastoid about once in eighty times. Therefore we consider that an *exploratory* mastoid operation is a well-studied and considered case is a justified measure. As an example of such a justification of an exploratory operation was the child admitted to the wards as a meningitis which was later changed to a diagnosis of a possible brain abscess. There was a history of otitis media but at the time of operation the evidence was so slight that the ear was generally considered as presenting all the external evidence of a normal ear. The operation revealed badly diseased mastoid cells and a localized pachymeningitis. This child after being considered to be a hopeless case, made a good recovery.

Two hundred and four histories have been taken from the files of the Babies Ward at the New York Post Graduate Medical School and Hospital. They included a variety of diagnosis as will be seen from the following list:

Bilateral purulent otitis media ..	18	Vomiting	1
Unilateral	5	Endocarditis ..	1
Mastoiditis	8	Scurvy	1
Bronchopneumonia	18	Eczema	1
Malnutrition ...	14	Secondary anemia	1
Acidosis	13	Convulsion	1
Dehydration ...	19	Meningism	1
Diarrhea	13	Pyloric stenosis ..	1
Acute gastro-en- teritis	5	Pneumonia	1
Bronchitis	3	Meningitis	1
Marasmus	3	Pyelitis	1
Rickets	2	Brain abscess ...	1
Cleft palate	2	Cerebral hemor- rhage	1
Feeding case	2	Adenitis	1
Terminal strepto- coccus menin- gitis	2	Congenital atonic colon	1
Septicemia	1	Hernia	1
		Celiac disease ...	1

All deaths were included in the group in the four-year period studied, unless they were obviously the result of some condition having no possible relation to upper respiratory infections, such as death following an appendix

operation. There has been little conscious selection of cases further than to rule out the purely surgical case even including those that came in with a diagnosis of mastoiditis and those medical cases in which there was a definite clear-cut picture of a medical condition which at best could have only a remote relationship to the upper respiratory tract. Acidosis, dehydration, vomiting, malnutrition, and bronchopneumonia were all included. A majority of the cases in which there was no satisfactory examination of the ears occurred in babies under one month of age or who came into the hospital in extremis.

Of the children, 42.6 per cent were under seven months of age. In this group there were twice the number of deaths and one-third the number of operations on the ears that are found in the larger group (57.8 per cent). The ages of the children ranged from two weeks to six and one-half years. In the younger age group, in many instances of which weight was taken daily, there were no gains in weight and often a moderate to severe loss with the onset of an upper respiratory infection. A red throat, or the appearance of congestion and edema in the mucous membrane of the nose, or the reddening of an ear, was invariably a sufficient reason for changing a good feeding history into a perfectly bad one. Of the 31 deaths in this series certainly having upper respiratory infection, 9 were operated on for mastoiditis, 3 within twenty-four hours of death. A similar operation was discussed in 11 of the remaining 22 cases and was delayed for various inadequate reasons.

It is my experience that operation is frequently delayed beyond the period of safety and I am convinced that the death rate in the cases mentioned in the foregoing could have been reduced considerably by immediate surgery, even though it be of an exploratory nature.

In an examination of 100 records from my private files I find that an upper respiratory infection always meant a stationary weight or a loss in weight, and that nearly all the deaths for a number of years in private practice have had their inception in a cold in the head.

Not infrequently the first evidence of improvement in the local condition was in the increasing interest in the food, a stopping of the regurgitation, an improvement in the condition of the bowels, and a gain in weight. This did not always mean a permanent recovery, though on not a few occasions it led to the postponement of an operation which might better have been done earlier.

There seems to be no reason why one should

operate routinely on a mastoid antrum for gastro-enteritis. Dehydration, acidosis, malnutrition, or bad feeding history are hardly indications for such interference. All these conditions I am convinced are frequently produced by an infection of the upper respiratory tract which includes the mastoid cells. Where this occurs, the ultimate prospect of recovery is improved if some method can be found to relieve the local condition. In so far as the ears are concerned myringotomy should be done at the first evidence of trouble in the ears in all small infants and feeding cases. A myringotomy, however, is usually insufficient and if the child continues a stationary weight or is losing weight and is beginning to show evidence of dehydration, a mastoid antrotomy should be considered.

There should be a closer cooperation between the otolaryngologist and the pediatrician. They should meet at the bedside of these cases and exchange opinions. In the end the pediatrician should decide when the time is opportune for operation. It is to be admitted that this sometimes requires courage, especially when the operation must be in the nature of an exploratory one. So far as I know we have not opened a normal mastoid in an infant or child. On the other hand, we have seen a number of autopsies at which *undiagnosed mastoids* were discovered.

When it comes to the nasopharynx, it must be confessed that the method of procedure is less clear. It is, of course, recognized that the tonsils and adenoids must on occasions be removed at an early age, but few of us have the courage to suggest such a procedure under the twentieth month and would prefer to wait longer. The maxillary and ethmoid sinuses are anatomically of interest at birth; and the sphenoidal and frontal sinuses at the sixth to the tenth year. It is more difficult to collect evidence of disturbance in nutrition in the very young as the result of purely nasopharyngeal infection, though it is usually recognized that a head cold is sufficient to stop a gain in weight which is not to be entirely explained by a loss of appetite. In older children such evidence is more easily found and all of us can probably remember a phenomenal growth and gain in weight after the removal of tonsils and adenoids; or the complete change in the outlook of a child in which an infected antrum was successfully treated. In our own experience x-ray pictures have not been very satisfactory in helping in the diagnosis of sinus infection or even of operable mastoids. Sinus infections are usually not as obvious as those infections occurring in the ear and produce their effects more slowly and are longer drawn out than is the case

with middle-ear disease. In both instances the more serious symptoms of malnutrition, dehydration, and acidosis are usually preceded by a period of a little fever and a stationary, or loss of, weight. The upper respiratory infection is rarely obvious while the gastro-intestinal symptoms and loss of weight are apt to be prominent. The only explanation for this disproportion between the focus and the general effect that I can offer is that it lies in the direction of a clinical change in the capacity of the infant or child to react to an infection or intoxication, following a primary infection; and it may be in the direction of immunity or of increased susceptibility. It is associated with anaphylaxis and is that form of immunity which in a general way is described as bacterial allergy. It often follows the absorption of bacterial protein from a focus of infection. It is quite certain that these children rarely have a septicemia or bacteremia; and it does not seem reasonable to suppose that their symptoms follow the swallowing of secretion from the nasopharynx or even are the result of a secondary infection of the gastro-intestinal tract.

The treatment does not depend upon changing the babies' formula but does quite naturally divide itself into preventive and immediate treatment. I have seen children with evidences of sinus infection whose parents and nurses were free of the disease, but I have yet to find the child whose parents or nurse had an active chronic upper respiratory infection who was entirely free of a similar infection. It is fairly well understood that colds are contagious, but there is still too little effort made to protect small children and infants from this contagion. It is also for this reason that home is generally speaking a safer place for babies than a hospital with its numerous opportunities for contact. Fresh air, controlled sunlight, and a properly balanced diet are all good preventive measures. It is as bad technic to remove tonsils and adenoids too late as it is to remove them too early and if the child continues to have many colds after the operation it is certain that the operation has been too late to prevent the infection of the sinuses. Cod liver oil is, as a rule, useful in increasing the resistance against upper respiratory infections and particularly those cod liver oils which are high in vitamin A. The concentrated oils which are obtained from halibut and salmon are usually of help in children which do not bear fats well or in which for any reason it is desirable to give a large dose without increasing the fat intake. Carotene, which is primary vitamin A of vegetable origin, makes it possible to greatly increase the vitamin A ef-

iciency of any fish oil which contains a reasonable amount of secondary vitamin A. So far as is known there are no ill effects from overdosage with vitamin A, so that it is proper to push the quantity well above what is perhaps needed. A deficiency of vitamin A, in animals at least, results in 100 per cent of upper respiratory infections so that it would seem wise to insure that every prospective mother, infant and small child should be insured against such a deficiency. I am personally convinced that the Alpine light properly controlled is of considerable value in raising the resistance of the individual against colds. Proper ventilation and the maintenance of an even temperature are of great importance.

The immediate treatment of an upper respiratory infection is of importance. Suction and remedies which are astringent to the mucous membrane of the nasopharynx seems to be about as far as we may venture in small infants. In older children the washing out of the antrum may be useful. I must admit that we have avoided operative procedure about the nose in small infants and still find unsurmountable difficulties in diagnosis. However, a recognition of a situation as it exists is important in a study of the group. In the ears there is a somewhat different situation. An infant showing signs of nutritional disturbance should have his ears opened on suspicion; and a mastoid antrotomy should be performed before he has reached a desperate pass.

The following statements are submitted for consideration:

1. Upper respiratory infections are a common cause of nutritional disturbances in children; in infants they may result in general symptoms, such as diarrhea, vomiting, dehydration, and acidosis.
2. The primary source of the infection is in the nasopharynx from which it may spread into all the sinuses including the middle ear.
3. Pathological processes may, and do, occasionally exist in the mastoid antra and in the sinuses with few or no diagnostic signs.

4. Roentgenograms when properly made and interpreted are sometimes useful. In small children, however, they should never be relied upon for a final diagnosis.

5. Mastoid antrotomy effects in a certain number of instances a cure of an apparently hopeless case. It should always be remembered that the operation is performed for a diseased mastoid (or sinus) and not for a gastro-enteritis. An exploratory mastoid antrotomy should be performed with less hesitancy than is at present the case. It is granted that in unscrupulous hands it would be radicalism at its worst.

6. Operation should not be delayed in cases where a diagnosis of operable mastoid is made.

7. We believe that the other sinuses are as important as the mastoid in producing nutritional disturbances but have to grant that the methods of diagnosis and treatment at the present moment are far from satisfactory.

8. The concentrated fish liver oils with our present means of increasing the vitamin A efficiency probably offer an immediate preventive measure of real importance.

I wish to thank Dr. Marvin Jones for helpful suggestions and his ready cooperation both in the wards and in his illuminating discussions of this whole matter in its relation to the well-being of children

A Radio Drive Against Quacks.—The Philadelphia County Medical Society, we are informed, has engaged Dr. Howard W. Haggard, popular author of "Devils, Drugs and Doctors," and "The Lame, the Halt, the Blind," to present a series of radio broadcasts in the interests of the ethical M. D. Members of the County Society are donating subscrip-

tions of \$15 each to pay for the series, and the benefits are expected far to outweigh the expense. The campaign covers thirteen weeks and is directed against quacks and patent medicines. Beside benefiting the profession, it will save the gullible public many thousands of dollars in money and do untold good in preserving their health.

ACUTE APPENDICITIS

By DENVER M. VICKERS, M.D., F.A.C.S.

From the Mary McClellan Hospital, Cambridge, N. Y.

Read at the meeting of the Fourth District Branch of the Medical Society of the State of New York, at Schenectady, October 11, 1932.

Appendicitis is an old story. Every young surgeon thinks he knows how to remove an appendix. Every medical student can recite the signs and symptoms. Every practitioner sees cases frequently. But, by that very token, the short study of a group of cases of acute appendicitis may be of more interest than the report of an isolated case of a rare disease.

In general, the mortality of acute appendicitis during the past few years has been increasing. In the United States Registration area, the deaths per 100,000 due to acute appendicitis¹ in 1900 was 9.7; in 1910, 11.4; in 1920, 13.4; and in 1929, 15.2. Analysis of a series of deaths by the Metropolitan Life Insurance Company² showed acute appendicitis second only to cancer as a cause of death in surgical disease. It is estimated that throughout the country, about 25,000 persons die annually from acute appendicitis or its complications.

To give a practical idea of this death rate, the mortality in New York City from measles, scarlet fever, diphtheria, whooping cough, all together, is 16.18, or practically the same as that of acute appendicitis; that from auto accidents is 17.25, and diabetes 23.54.

It is recorded³ that the European rates are much lower; the combined average being around 5.6. The reasons for this lower figure have not been explained. Whether the methods of compiling the figures are comparable or not, I do not know. In the literature, their methods of treating appendicitis do not seem to vary essentially from our own, and I see no reason for any great variation in results.

Therefore, these 320 consecutive cases of acute appendicitis were taken from our own files. These are all cases I have seen personally, and have been operated on by Dr. Fortune, my colleague, or myself. They are all acute, clinically, pathologically or both. Let us then tabulate these and see where we stand.

Chronic appendicitis is another question. What its diagnostic criteria are, whether or not there is such a disease, what the chances are of its cure, that is not the present story. I have excluded all such cases from this series.

In acute appendicitis I offer no new or startling methods of diagnosis or cure. We use standard technic throughout. Our methods are those I have seen used in many other clinics and hospitals. I believe there is no royal road to success, but in the difficult case there is no disease that calls for more accurate judgment, more balanced technic, and more careful postoperative care.

In the diagnosis of this disease there are definitely two classes of cases: First, the textbook type of case, with the definite progression of symptoms, and characteristic physical signs. These occupy perhaps 50 per cent of the cases. Second, the atypical cases, that may severely tax your diagnostic ability, making another 50 per cent. These may begin with right-sided pain, or no pain at all; they may have vomiting early or late or not at all, and give nothing like the textbook history and physical examination.

It is well, too, to bear in mind that appendicitis may be pathologically of two types; the acute inflammation of the wall of the organ, a relatively harmless disease, or a sudden obstruction of the lumen, which may be rapidly fatal.

The first gives rise in pulse and temperature, vomiting, aching pain, and local tenderness. The second gives more the picture of acute intestinal obstruction, with sudden onset, spasms of pain, vomiting, but little or no rise in pulse and temperature.

The pathological observation of these two types of cases explains the reasons for the variable results in delayed operating. Clinically it is of minor importance, for I believe we should operate as soon as the diagnosis of acute appendicitis is made, whichever type we suspect. However, it is the clinical study of the pathology of the first few hours in this second group of cases, that will bring results. The diagnosis and removal of an acutely obstructed appendix is still one of the triumphs of modern surgery.

Let us take, then, our series of 320 unselected cases and see who has appendicitis.

In this series, we find 186 male and 134 female patients; that is, 58 per cent male and 42 per cent female, which is about the usual reported ratio (Chart 1).

The chart for the age distribution (Chart 2) explains itself. We see that the maximum incidence is between 15 and 20 years. The youngest case in this series was 17 months

and the oldest 75 years. Since we started this tabulation we have had one case in a man aged 86, with good recovery. Thus appendicitis may be found at almost any age, but is more common in adolescence and in adults.

The general mortality in our whole series was 5.43 per cent.

Boland¹ from Georgia, at the Section on Surgery at the A.M.A. Convention in 1932, tabulated 4,270 cases operated on by 197

of unoperated appendicitis I could find, is in the Georgia statistics¹, which shows 46 not operated; half refused operation and half were treated, with 5 known deaths, a mortality of 11 per cent.

Of the others in our own series, we operated on 193 cases, in which it did not seem necessary to drain the peritoneum or in which an abscess had not formed. Of these, none died; that is, there was a mortality of 0 per cent. Of course, if we keep on operating

Chart 1—Acute Appendicitis and Sex Distribution

Chart 2—Age Incidence in Acute Appendicitis

surgeons and found a mortality of 4.4 per cent. Weeden⁴ in New York reported 1,588 cases with a mortality of 4.9 per cent. Black⁵ before the Western Surgical Association found a mortality of 4.88 per cent in 83,000 cases. Tasher⁶ reported 361 acute cases with a mortality of 6.4 per cent. McKinty⁷ in Winnipeg studied 17,916 British and American cases and came to the conclusion that the average mortality is around 6 per cent, and that a large percentage of the deaths must be charged to diffuse peritonitis. So these figures agree fairly well.

Now, let us look at the mortality and the type of procedure necessary (Chart 3).

In this series there were 7 unoperated cases. Let it be understood that we believe that once the diagnosis of acute appendicitis is made, operation should be advised, but in this series there were 7 cases that either refused operation, or were in too poor condition for operation, or for some other reason were not operated on. Of these, 2 died (28 per cent).

The only other tabulation of the mortality

long enough sooner or later we will run into some of the accidents of surgery, which will give a small mortality, but so far, the record is clear. Appendectomy is not yet strictly comparable to having a haircut.

Of the others, in 120 it was necessary to drain. In these, there were 17 deaths, or a mortality of 14.1 per cent. This mortality is apparently greater in recent years, for conversely, we have been draining fewer and fewer cases. Or at least, after the appendix has been removed, if the peritoneum is not grossly contaminated, we close the peritoneum, and at times leave the fascia open for secondary suture or granulation. This procedure saves the patient time in the hospital, saves fascia with stronger repair, and clinically is very satisfactory.

Some of the acutely ill patients in this group had merely drainage of the peritoneum, without removal of the appendix. No great degree of time or trauma to the intestines should be used to find an appendix in the presence of a spreading peritonitis. If the

organ is not readily demonstrated, drainage only is done.

Theoretically, in the recovered cases of this type, we should reoperate later to remove the appendix, but in all our cases of this class, we have had no recurrence of symptoms. In the drainage cases, most of the cultures showed *B. coli*. The streptococcus gave a distinctly poor prognosis.

We believe, though, that the appendix should be removed at the primary operation

If the appendix can be easily found and removed, we sew up those cases of slight or beginning peritonitis, knowing that the peritoneum can take care of considerable infection. But if the appendix was not removed, or if the amount of septic fluid is at all large, we leave cigaret drains well down in the peritoneal cavity, to be gradually removed. Stiff rubber tubes or bare gauze should not be used as they further traumatize the intestines. The clean cases are obviously completely sutured.

if the peritoneal reaction is not too great. To remove an acutely inflamed, friable appendix through a small incision, without traumatizing the rest of the peritoneum or bowel, is a technical trick well worth study and practice. The ligating of a mesoappendix deep in the wound, with imperfect visualization is difficult for the surgeon, but best for the patient, avoiding traction on potentially infected vessels and lymphatics.

I hold no brief for any one incision. With careful examination, one may get a hint as to whether the organ is pelvic or far to the right. In males, the muscle-splitting McBurney incision usually gives good access to the appendix, if it is in the usual location, though allowing little chance for exploration, which should not be done anyway if the diagnosis is correct. In females, the difficulty of differential diagnosis may mean more frequent right rectus, or even midline incisions, though if the case is septic this means dragging infected matter across an uninfected peritoneum.

For anesthesia, we have used ether, local and spinal. Ether is still the old reliable, though I believe many postoperative herniae start in the straining after ether. Nitrous oxide is of value at times. Spinal anesthesia theoretically induces greater peristalsis, though it makes exploration easy by relaxing the abdominal wall. Local anesthesia, though slow, is of great value in the more critically ill patients, and with care, the whole operation can be done satisfactorily. Recently we have used sodium amytal to give a "basal" anesthesia in those patients who can retain it.

Promptness in operating has been talked about for years. Let us see how important this is (Chart 4). In this series, the average duration of symptoms in the clean cases, before operation, was 34.3 hours. These varied, of course, rather widely, I suppose, as to whether the disease was obstructive or straight inflammatory, but the figure is the average.

Of the drained cases, the average duration of symptoms preoperative was 76 hours.

And in the fatal cases, the average time was 103.4 hours, a higher figure than the other two. The conclusion is obvious.

Bower⁸, of Philadelphia, in recognizing this factor, said that in surgery of the appendix, so far as mortality is concerned, we have reached about the same stage as in carcinoma of the breast. From a technical standpoint, little more can be done, but a great deal has been done by publicity.

We take the admission temperature by rec-

derful for some things but terrible for appendicitis. Bower holds cathartics responsible for 92 per cent of the deaths in his series. This matter was commented upon editorially in the *Journal of the A. M. A.*⁹ not long ago, stating that in a great majority of all severe cases, including practically all who had early and hopeless peritonitis, a cathartic had been given soon after the onset of the disease. Certainly we cannot hope to reduce the mortality of acute appendicitis till the public in gen-

Chart 5.—Acute Appendicitis. Temperature and Leukocyte Counts

tum (Chart 5). The average temperatures of these three groups are as follows: in the clean cases, the admission temperature was 100.1; in the drained cases, the average temperature was slightly higher at 101.4; and in the fatal cases, the temperature was 102.5.

In the case of the total leukocyte counts, the figures do not increase so smoothly. The figure for the average clean case is 12,700. For the average drained case, it is 17,250. And for the average fatal case, 15,100.

In other words, the average case of acute appendicitis has very little rise in temperature until the disease spreads to the peritoneum. By the figures, a temperature by rectum of over 101, gives better than even odds that the appendix is ruptured. And in the more critically ill patients, a white count below 15,000 is of poor prognostic value.

Of our fatal cases, and drained cases, a large percentage had cathartics. Appendicitis is obviously frequent in the youngsters, who are apt to come under the care of maternal castor oil. Castor oil is certainly won-

derful for some things but terrible for appendicitis. Bower holds cathartics responsible for 92 per cent of the deaths in his series. This matter was commented upon editorially in the *Journal of the A. M. A.*⁹ not long ago, stating that in a great majority of all severe cases, including practically all who had early and hopeless peritonitis, a cathartic had been given soon after the onset of the disease. Certainly we cannot hope to reduce the mortality of acute appendicitis till the public in gen-

eral and mothers in particular recognize the fact that a stomach ache is not always an indication for a dose of castor oil.

SUMMARY

1. Acute appendicitis in our series is largely a disease of young and young adult life.
2. There is an average mortality of from 4 to 6 per cent. This mortality often follows the taking of vigorous cathartics.
3. The mortality is directly proportional to the length of time elapsing between the time the patient is taken ill and the time he is operated on.
4. Operation for appendicitis before the disease has spread beyond the appendix is accompanied by very slight risk.

THE EXPLOITATION OF VITAMIN A

By S. W. CLAUSEN, M.D.

From the Department of Pediatrics, School of Medicine of the University of Rochester, Rochester, N. Y.

Read before the Section on Pediatrics at the annual meeting of the Medical Society of the State of New York, New York, N. Y., April 5, 1933.

Vitamin deficiencies in animals may lead to decreased resistance to infection. This is especially true of vitamin A. This fact has led to the belief that susceptibility to infections in human beings may be due to use of food which lacks adequate amounts of vitamins, even though other evidence of vitamin deficiency is not apparent clinically. A condition of partial or latent deficiency is then said to exist. If the administration of vitamins to a group of individuals should lead to a striking lowering in the incidence of respiratory infection, this thesis would be established. Different investigators, however, have reached diametrically opposite conclusions. For example, Mellanby¹ does not hesitate to term vitamin A "the antiinfective vitamin"; Sawyer² by administering cod liver oil to industrial workers is able to reduce the incidence of colds from 55 per cent in a control group to 32 per cent. On the other hand, Lewis and Barenberg³ show that in a group of infants in the hospital, cod liver oil does not lessen the number or severity of respiratory infections; and Sutliff⁴ shows that cod liver oil will not prevent otitis media as a complication of scarlet fever. In order to reconcile these conflictive observations, it is necessary to assume a latent deficiency in cases where benefit has followed the use of vitamin A. Although the assumption of a latent deficiency might be justified, it could be more definitely established if evidence of a direct sort could be secured. In the present communication, evidence of this kind is presented. At the present time, some criterion of latent deficiency of vitamin A is needed, because various preparations of the concentrated vitamin A and of its precursor, carotene, have appeared on the market. The claims made for these preparations by the manufacturers are naturally based upon the favorable clinical reports, whereas adverse reports are ignored.

We have based our studies upon the carotinoid pigment of the blood plasma, as determined by the method of Connor⁵. These studies were made because carotene is the precursor of vitamin A. We have shown that carotinoids appear in the blood after the ingestion of pigmented vegetables or of carotene in oil; that they disappear gradually when such materials are omitted from the diet; and more rapidly during an infection. In any given person, the level tends to remain rather

fixed during health; but the levels in different persons vary widely. We are well aware that what we have determined is a mixture of carotene, xanthophylls, and possibly other carotinoids; whereas carotene alone is to be regarded as the precursor of vitamin A. However, as these pigments in foods are always associated with vitamin A activity, and as a definite regularity appears in our results, we feel some confidence in the method.

We will present first a study of plasma carotinoids in 1,322 children over two years old (Fig. 1). The levels are given in arbitrary units, each unit being approximately 1 gamma (0.001 mg.) per 100 c.c. The number of cases falling within limits of 20 units is plotted over the midpoint of each interval. In children free of infection when examined, the greatest number of cases fall within 80 to 120 units, but there is a very wide range. In children with mild infection, there is a distinct fall in plasma carotinoids. In those with severe infection, this fall becomes still more marked. Repeated observation of a number of individual cases has shown beyond question that the fall in carotinoids of the plasma does not precede infection, but results from it. This fall is due largely to lessened food intake. The return to the initial level (that preceded the infection) takes place within ten days to two weeks after the temperature becomes normal. The lowering of plasma carotinoids during infection, therefore, cannot be used to argue that insufficient carotene intake predisposes to infection.

The records of all cases here discussed were examined by the author for a history of repeated respiratory infection. The uncertainty of this sort of evidence is acknowledged; but cases were included only when they could be clearly classified as "susceptible" or "not susceptible." The percentage of susceptible children in each group included within the limits of 20 units of carotinoids was calculated. In the healthy children, it was found that the percentage of children susceptible to repeated respiratory infection is higher in those with low plasma carotinoids; and that the susceptibility falls rather suddenly at carotinoid values of 80 units. Above 140 units, the susceptibility to repeated infection again rises. We can thus distinguish three zones: plasma carotinoids below 80 units, 301 children, 34.5 per cent susceptible; 80 to 160 units, 341 children, 23.7 per cent susceptible; over 160 units, 87 children, 37 per cent sus-

ceptible. In the middle zone, 23.7 per cent of the children are susceptible, and this rate of susceptibility does not decrease when the

ceptibility to lack of vitamin A; we are entitled to attribute only the increase in the rate to this factor, that is, 10.8 per cent, the difference between 34.5 and 23.7 per cent. Consequently, 32 children in this zone, and none of the other 729 children, can be assumed to owe their susceptibility to a deficiency of vitamin A. In other words, only 4.5 per cent of the children, healthy when examined, may have a relative deficiency of vitamin A. Similar zones can be distinguished in children with mild and with severe infections. In other words, the lowering of carotinoids due to the infection present at the time of observation, does not obscure the occurrence of the three zones. Calculation shows that in the children with mild infections, 5.4 per cent might owe their repeated infections to low carotinoids; and in the children with severe infections, 41 per cent. The correspondence in these figures is probably significant. It means that in the children studied, susceptibility to repeated infection is due to low carotinoids in not more than 5 per cent. If an effort were to be made to improve resistance by administering carotene in some form to half of the group, the other half serving as controls, a statistical analysis would fail to show a significant difference. Nevertheless, a few individuals would be benefited; but by including them among many

Fig 2

carotinoids rise. This may be taken to represent susceptibility which is not due to deficiency of vitamin A. We may reasonably assume that 23.7 per cent of the children in the lowest zone also do not owe their sus-

unbenefited ones, the real effect would be obscured. In these days when the statistical method is being so widely applied to therapeutic studies, we must note this important limitation of its value. Obviously, some

means are required for selecting the group of persons in whom studies are to be made. It is suggested that in studies of the effect of administering carotene, determinations be made of plasma carotinoids.

The significance of increased susceptibility to infection of children with high plasma carotinoids is not clear. By a simple calculation it can be shown that high carotinoids are associated with increase of susceptibility in 1.2 per cent of the healthy children, in 0.9 per cent of those with mild infection, and in 8.1 per cent of those with severe infection. Possibly certain individuals cannot utilize carotene readily. We have observed diabetics who were susceptible to infection while plasma carotinoids were high, as well as a few cases of xanthosis cutis, with marked susceptibility to infection. On the other hand,

in Figs. 2 and 3, no benefit resulted, either in the temperature or in the number of complications. It would, of course, take a much larger series to settle this question. At this time we shall only point out that the administration of carotene caused a definite rise in the plasma carotinoids (Fig. 4). This rise was not apparent in the first week or ten days; nor was it so marked in cases complicated at the onset, or in those who had fever, after the first two weeks after the onset. In this series, we determined also the vitamin A content of the plasma by the Price-Carr method, a correction being made for the effect of carotene upon the reagent. It was shown that the administration of carotene causes a rise in the vitamin A of the plasma. This increase also is apparent only after the first two weeks and is less in those cases with

LEVEL OF VITAMINE-A IN PLASMA, AS INFLUENCED BY ORAL ADMINISTRATION OF CAROTENE DURING SCARLET FEVER

Fig. 3

we have not ascertained the nature of the carotinoids in the cases here presented. In a few others with marked elevation of carotinoids a high xanthophyll level was present.

In those children who were severely infected when examined, the number in the zone of higher carotinoids was +5 per cent of all; whereas in the children with no or mild infections, the high zone included only 10 to 15 per cent of all. Possibly the group of children with severe infections included a large number who were unable to convert their stores of carotene readily into vitamin A. The suggestion is obvious that the administration of additional carotene during an infection may be of no value, either on this account, or because it is not readily absorbed.

Carotene was administered to 63 cases of scarlet fever. Alternate cases received 0.3 mg. per kilogram per day in oil. As shown

continued fever. Five or six days after the fall in temperature, the vitamin A rises above normal; after another six or seven days, it falls to a new low level. There is some indication that administration of carotene may lessen this secondary fall. Whether such an effect would be beneficial we cannot say.

The failure of obvious benefit from administration of carotene during the course of

TABLE I—EFFECT OF ORAL ADMINISTRATION OF CAROTENE DURING SCARLET FEVER UPON TEMPERATURE

	Carotene	16	39.9	39.4	38.7	38.4	38.6	38.4 37.9

scarlet fever may be due to the fact that the number of our cases is small, or that the control groups are not strictly comparable. It is not due to the failure of absorption of the carotene nor to the failure of its conversion to vitamin A. We are inclined to think that the cases studied did not suffer from any

due to faulty absorption. At the present time, several preparations of carotene have appeared on the market, heralded by unwarranted claims. Any value which these preparations may possess will not be apparent unless due caution is used in prescribing them only where actually needed. There is also

VITAMIN A OF BLOOD IN SCARLET FEVER EFFECT OF ADMINISTERING CAROTENE

Fig 4

deficiency of vitamin A and that no benefit should have been expected.

Discussion and Application.—In a group of children over two years of age, evidence is presented that relative deficiency of vitamin A could have existed in only about 5 per cent. This conclusion is based upon a consideration of the increased susceptibility to infections in the groups with low plasma carotinoids. It is pointed out that confusion in the clinical evaluation of carotene as an anti-infective agent will continue unless some criterion is developed for selecting cases which really suffer from relative deficiency of vitamin A. It is shown that failure to obtain beneficial ef-

fects from administration of carotene is not no reason to believe that carotene in oil is of greater value than carotene in vegetables.

Mothers Who Might Have Lived

The fires of discussion over the record of maternal mortality in the United States, instead of dying down, seem to be flaming higher and hotter. It was the topic on January 18th, at the annual meeting of the Maternity Center Association at the Waldorf-Astoria. A dozen remedies were brought forward by various speakers, and nearly everybody concerned with childbirth received a rap from somebody's cudgel—doctors, midwives, hospitals, medical schools, and even the city government, which ought to extend prenatal and confinement care.

The verdict issued in November by a joint Committee on Maternal Mortality from the New York Academy of Medicine and the New York Obstetrical Society, it will be remembered, was that 65.8 of the maternal deaths included in its investigation might have been prevented "if the care of the woman had been proper in all respects."

The obstetricians certainly have the courage of their convictions in bringing the pitiless spotlight of publicity to bear on a situation for which the profession must accept much of the blame. The criticisms made in medical circles mention needless operating, incompetent services, unsuitable environment, the advantages and ease of operative deliveries in smaller hospitals, the need for the control of hitherto unsupervised institutions and better instruction and control of midwives as points which need attention.

This grave situation is at once sobering and stimulating. It is stimulating because it calls attention sharply again to an opportunity to push the eternal campaign for life-saving in a new direction. The high rate of maternal mortality in this country has long been known, entirely too long, in fact. Other mortality rates have been driven downward. The general mortality rate, for example, has been cut more than 25 per cent, infant mortality cut something like 45 per cent, and the death rate from tuberculosis cut 65 per cent.

In the face of these splendid advances, however, the maternal death rate has shown little or no improvement. We pride ourselves on our increasing knowledge and skill in prenatal care, sanitation, and asepsis, we think we have improved our methods in modern obstetrics, and we believe our hospital facilities are the last word, yet there stands the record in cold figures.

Among all the countries reporting on maternal mortality, the United States and Scotland lead the world, two countries that suppose themselves to stand at or near the top in medical skill. As we are reminded by the Statistical Bulletin of the Metropolitan Life Insurance Company, the maternal mortality rate in the United States Birth Registration States in 1915, the first year for which the figures are available, was 6.1 per 1,000 live births; in 1932, the same area showed a rate of 5.9, while the average rate for the area during 1928-1932 was 6.0.

It is true that few other countries have shown any improvement, and eight, in fact, have shown an increase in maternal mortality since 1910, but that does not excuse us from our plain duty. If any such percentage of these deaths are preventable, as the committee of the Academy aver, an amazing opportunity lies invitingly before us. The committee in its recommendations stresses the need for better education and training of physicians and midwives, the relative safety of delivery at home, and more rigid measures for asepsis in obstetrical cases in hospitals. Earlier studies support the belief of the committee that two-thirds of the lives now lost can be saved. Every death means that some home has lost the one who makes it a home. Here is a challenge to the best and highest skill that America possesses, to better the record in the year before us.

Helpful Advice for Nazi Invalids

A clever non-Jewish physician, Dr. Lukat-chewsky, writes an amusing communication to a newspaper in Basle, Switzerland, that is attracting the attention of the medical press. He remarks that since the Jewish spirit is to be destroyed in every branch of life according to the National Socialist doctrines, he is anxious to provide a medical guide so that consistent anti-Semites should know what to avoid when they are ill.

A Nazi who has syphilis must not allow himself to be cured by salvarsan, because it is the discovery of the Jew, Ehrlich. He must not even take steps to find out whether he has syphilis because the Wassermann reaction which is used for the purpose is the discovery of a Jew. If he thinks he has gonorrhea, he must not seek to establish the fact, because again he will be using the method of a Jew, Neisser. A Nazi, who has heart disease, must not use digitalis, which comes from a Jew, Ludwig Traube. If he has a toothache he will not use cocaine, or he will be benefiting by the work of a Jew, Salomon Stricker. Typhus must not be treated or he will have to benefit by the discoveries of the Jews, Widal and Weill. If he has diabetes he must not use insulin, because of the research work of the Jew, Minkowsky. If he has a headache, he must shun pyramidon and antipyrin (Spiro and Eilege). Anti-Semites who have convulsions must put up with them for it was a Jew, Oscar Liebreich, who thought of chloral hydrate. The same with psychic ailments, Freud is the father of psychoanalysis.

Anti-Semitic doctors must jettison all discoveries and improvements by the Nobel prize men Volitzer, Barangaj, Otto Warburg, the dermatologists, Judassohn, Bruno Bloch, Unna, the neurologists Mendl, Oppenheim, Kronecker, Benedikt, the lung specialist Fraenkel, of the surgeon Istael, anatomist Henle, and others.

Health and Beauty

Someone had estimated that the regular customers of the "beauty" industry in the United States number over 20,000,000 women, or five times as many as the total number of men enrolled under the American flag during the World War. Not all the four million men smelt powder, but every one of the twenty million women face it without flinching. The procession passing in and out of the beauty par-

lors spends more than half a billion dollars a year, we are told, or more than one and a half million dollars a day. We are further informed that this is more than was spent last year on automobile and truck bodies, although the connection is not quite clear.

What our statistical friend fails to mention is that if these women realized the beauty that health brings, some of the millions of dollars now spent in beauty parlors might go, with better results, for healing the big and little illnesses that dim the eye, line the face, droop the erect figure, and play havoc generally with good looks.

Every doctor can tell of beauty that has been brought back by restored health. Yet the big parade of women chasing beauty passes the doctor's office by, and pours a flood of gold into the purses of the beauticians. If the truth could only be implanted in woman's mind that there is no beauty like good health, the physicians would have a truly golden opportunity to improve the health and looks of the nation.

Making the Public Too Health-conscious

A physician in the Middle West took the trouble to jot down a list of the various health rules broadcast by radio, newspapers, etc., as essential to his well-being, and found that if he performed all the exercises, rites and stunts that were demanded, it would take from five to eight hours a day, enough to break down any man below par physically who might try to gain health by this route. The public is deluged, inundated, swamped, by free advice on health. Forty magazines have health articles in every issue; the daily papers run a dozen syndicated health columns; books drop from the presses in thousands, and the land is filled with pamphlets, lectures, health instruction in the schools by physicians, nurses, and teachers. "On the side" are the loud claims of quacks, charlatans and shysters, and advertisers step in to capitalize it all by vending their products.

Beyond question untold good has been done by the great campaign of public health education, but in some cases it has gone to a point where people are so busy keeping their health that they never have time to use or enjoy it. They are so possessed by the fear of disease that they are in a panic over it. This Middle Western physician was told solemnly by a salesman that every nook and corner of his house ought to be the same temperature day

and night, week in and week out, and was assured that the health of his family depended on it.

A vacuum cleaner salesman told him that the emptying of a vacuum-cleaner bag was deadly, though he could not explain why the germs, so fatal in the bag, had not killed them all when in the rug. The electric refrigerator man warned him of ptomaines in the icebox. Aluminum-ware people tried to frighten the family with perils of swallowing slivers from enamel utensils, while the enamel-ware salesman came back with the claim that salts of aluminum cause cancers. All in all, it seems a miracle that anyone is alive.

The "safety-first" campaign in the schools is excellent in many ways, but if carried too far it will make us a nation of mollycoddles, in the view of this physician, Dr. Thurman B. Rice, of Indianapolis, as expressed in a paper read at a medical meeting in his city. "God pity us," he exclaims, "if we should ever have to go to war with an army of 'safety-first' boys." And the teachers are doing something more, as he sees it. They are making their health teaching unattractive by dinging everything into the child's head as a task and a duty until the child hates it. Long-faced, sour-minded teachers of hygiene are doing more harm than good. Vitamins are in attractive foods as well as unattractive ones. Baths, tooth-brushing, walking, and playing in the sun are pleasures and should not be made disagreeable.

A tendency has also sprung up to make health exercises expensive, when just the opposite should be the rule. Simple foods, outdoor games, fresh air, sunshine, water, home amusements, are ideal for health and cost little or nothing. A whole food program, avers Dr. Rice, can be summed up in one sentence, and he challenges any member of the medical profession or any dietitian to add one important word or phrase to the following sentence:

"A balanced ration is an abundance of a variety of clean, wholesome, not too denatured food, carefully prepared, attractively served, and eaten in peace and contentment." If this menu lacks anything, he feels sure it will be adequately supplemented if common sense is used and particular preference shown for the protective foods—milk, vegetables, and fruit.

Dr. Rice should not be misunderstood as criticizing sound public-health instruction. He

favors it strongly. What he objects to is overdoing it to the point where people are thrown into a panic. He has in mind a mother who is so obsessed that she spends nearly all her time fussing with her four-year-old child. No germ could possibly get to that child without a stiff fight. The little girl has never been permitted to play on the floor. She wears heavy cuffs so she cannot put things in her mouth. Theoretically, she should take the prize at a health exhibit. Actually, she is neurotic, pale, thin, bored with the task of living. Her temperature is taken every day, her weight recorded, and she has been treated for a long string of ailments, mostly no doubt imaginary. The mother is "health-conscious" to the point where ill-health is the result.

Teach the public the rules of health, says Dr. Rice, but remember that "it is not well for the health of the public to make it excessively health-conscious."

Handy-Guides to Homicides

A "mystery" murder novel that has had a considerable vogue this winter is of particular interest to the medical profession, because murder is committed by putting a capsule filled with poison into the box of medicinal capsules prescribed by the physician. When the patient took the capsule of poison, he was seized with violent pains, and expired. The diabolical ingenuity of the murderer appeared when the autopsy showed no trace of poison of any kind. The wall of the patient's stomach was found to be perforated, and this was clearly the cause of death, but the physician declared himself "completely satisfied" that the victim "died from causes which can only be described as natural," because he could find no other cause. A gastric ulcer could have made the perforation, he said, and the patient was suffering from gastric trouble, so he was convinced that his verdict was sound.

The hero of the story, however, was not satisfied. An earlier attempt had been made to poison the victim with arsenic, and he was convinced that the victim had been poisoned—if not with arsenic, then with some other drug. There is not room here to relate the entire story of his investigations, but, to make a long story short, he found that the murderer had filled the fatal capsule with a white alkaline metallic element that would burn a perforation in the wall of the stomach and unite with the digestive juices to form common salt,

which might be found quite naturally in anyone's stomach.

It is not necessary to name the substance, as every physician will recognize it at once, but the novelist names it, over and over, and gives sufficient directions so that almost anyone could prepare a fatal capsule and slip it into the box used by the "rich uncle" or the "hated rival."

The craze for murder mystery tales was bound to lead to a plain guide to murder like this sooner or later. The very essence of such a story is to have a killing so satanically clever as to baffle everybody except the Sherlock Holmes whose eye can penetrate all secrets and whose hand can entangle all webs. So our printing presses are turning out thousands and millions of copies of books describing murders that are almost impossible to detect. True, some of them are ludicrous. One villain in a recent story, for example, stabbed his victim with an icicle, so that no trace of the weapon was found—only a puddle of water, which naturally showed no fingerprints! But no epidemic of icicle murders has been ensued.

It is a very different thing, however, when an author gives plain directions for mixing poison with the doctor's medicine, with the added assurance that a postmortem will never find it. There are plenty of murders blazoned on the front pages of our newspapers now. How many more go unsuspected nobody knows except the guilty. But it is surely not necessary to crowd the shelves of the bookstores and public libraries with volumes telling multitudes of readers just how to go about it without fear of detection.

Let the Laity Stop Trying to Do the Doctors' Thinking for Them!

The skill of the expert diagnostician in putting his finger on the sore spot was displayed by Dr. Walter T. Dannreuther in his inaugural address as President of the Medical Society of the County of New York. The sore point is the effort of "others attempting to do our thinking for us," and "the impotence of amateur influences to dabble independently in medical matters."

Everybody had more say in what to do for the sick, apparently, than the doctor, and arrangements are made to pay everybody, too, except the doctor. "A glaring example," as he well remarks, are the Workmen's Com-

pensation Insurance Laws of New York State. If the medical profession had been permitted originally to have a part in framing these laws, "employer, employee, and doctor would not now be so dissatisfied with their operation, nor would it have been necessary for the Governor to appoint a committee in 1933 to recommend amendments to correct existing evils."

Next we have the majority report of the Committee on the Costs of Medical Care, "which proposes to mechanize the medical profession, establish group practice, and foist state medicine upon the American people." Its fallacies, Dr. Dannreuther declares, "are a menace to the public, destructive to the ideals of the medical profession, and bad sociology." Wherever tried abroad, this scheme has "definitely lowered" the level of medical service.

Almost all the current difficulties of organized medicine, in fact, "may be fairly ascribed to extraneous influences: legislative, governmental, industrial, sociological and institutional," and Dr. Dannreuther remarks caustically that "there are so many self-anointed reformers who have shown a willingness to make our affairs their business that a concerted and sustained campaign to direct our own destiny is imperative."

Then, there are the misguided philanthropists. They too are trying to do the doctors' thinking for them, and we are assured that they are "the most pernicious influence which has affected the practice of medicine in recent years." True, the profession is grateful to these liberal contributors, "but wealth is no criterion of good judgment or honesty of purpose, and all philanthropists do not seek the advice of unselfish physicians who have a correct perspective of medical economics." And not all these "volunteer uplifters" are "without a thought of personal gain, despite their avowed purposes."

A spree of hospital-building has also been indulged in by national, state, county, and city governments in recent years such as the world has never seen before in its history. "Millions of the taxpayers' money," observes Dr. Dannreuther, "have been expended on government hospitals which surpass in size and magnificence most of the private institutions and which even the politicians are finding difficulty in filling with free patients." Many of them are located "without any apparent regard for the present or future needs of the population."

The entire country is over-hospitalized, in the doctor's opinion; it has been "on a building splurge, erecting medical emporia so elaborately equipped that they are economically unsound." What would be better, he thinks, would be extension of medical care in the patient's home, which would relieve overcrowding in hospitals, "while at the same time it would cost the city less to pay the family physician a modest fee than it does to maintain the patient in a charitable institution."

All these lay interferences in the doctor's field have gone far enough, in fact, too far. Medicine "must oppose outside meddling and selfish commercialism," declares Dr. Dannreuther. "It is prepared," he admits, "to co-operate in every way to preserve the health of the individual and the community, but it is entitled to an independent career, adequate compensation from those able to pay, and the right to control its own affairs."

A Report on the Plight of Science in Germany

So much has been said about the physicians, professors, and other scientists who have been driven out of Germany that many of us have forgotten to ask what the situation may be of those who still remain there. Dr. Alice Hamilton, of the Harvard Medical School, spent three months in Germany in the early part of last year and makes a remarkable report of what she found there, in the January Harpers Magazine. She is an expert witness, too, for she did graduate work in medicine at the Universities of Leipzig and Munich in her younger days, when the German universities were regarded as the bulwarks of freedom in scientific research, and so is well qualified to speak of the contrast they present now.

Hitler and his party are not only molding the entire German people to their hearts' desire, it seems, but Dr. Hamilton reports that they have decided that "intellectualism" is to be discouraged. "Intellectual training does not serve in a moment when steel is needed," declares Hitler, in so many words in his book, "Mein Kampf." "Discipline and obedience" are needed rather than "intelligence and intellectual independence." More unmistakable was the blunt announcement of the new Commissar for Education, Rust, last April, that "unprejudiced, objective, scientific teaching, which is blind to the spiritual changes within the nation, will no longer be tolerated."

And Dr. Hamilton testifies that it was not tolerated. When she reached Germany last April, "academic heads were falling right and left." She was told that "no research work is possible in German universities now." One professor, now discharged, said: "For research one needs quiet, security, opportunity for concentration, none of which we now possess. You cannot carry on any real work with a sword of Damocles hanging over your head." Some might think it comical, if it were not so serious, to learn that one professor, Bluntschli, "was forbidden to lecture on anatomy because someone discovered that he was a member of the League for Human Rights."

Medical students, so we are told further, must fall in line with the new gospel. Habering writes in a German medical journal: "It is necessary to remove the medical student from the influence of intellectuals whose minds range freely, if he is to be deeply rooted in the national life." Reverence for the past is to be inculcated rather than curiosity about the undiscovered. "A very concrete and most disastrous measure," says Dr. Hamilton, "aimed against scientific inquiry, has been adopted only recently, namely, the prohibition of animal experimentation. This means that practically all advance in the fundamental branches dealing with normal and diseased living matter comes to an end in that country which was for years in the foreground in just those fields."

It is not in the province of this journal to say that the Hitler program in Germany is right or wrong, but Dr. Hamilton's report is of supreme interest to all who hold dear the welfare of pure science in the land made illustrious by the long roster of famous German savants.

Protection of the People Against Unlicensed Attempts to Practice Medicine

For a long time the medical profession has heard but little of legal efforts to protect the public against damage that might follow in the wake of those who impudently, without training, attempt to diagnose, and treat, disease, without the license provided for in the laws of the state.

Recently one such person has been brought to book. One Domenico Mancini, of Endicott, N. Y., was fined \$75 and sentenced to six months in Broome County jail for prac-

ticing medicine without a license. The jail sentence was suspended during good behavior for one year.

It is to be hoped that the members of the Medical Society of the State of New York will observe carefully any such situations that may come under their notice, that they will attempt to secure facts and then transmit their information to the Boards of Censors of their County Societies. Far too often, individuals such as Mancini have carried on without interference because no one felt impelled to bother himself until the tread of the unlicensed boot had crushed his medical toe.

The matter goes much farther. In these days, the charlatans of all kinds stage their acts, and the many "fringe-of-medicine" performers bark into their booths the unsuspecting and those of the mental grade supposed to be born at the rate of one every minute.

It is time that the people be better protected. No doubt, the doctors far and wide dislike to search out and attack the unlicensed "magic" men, the unlicensed fakirs, those even who have a part license to invade the practice of medicine, the fringe of medicine technicians but who still are dangerous. They hesitate for fear that they may be accused of trying to protect their own pocket books.

The JOURNAL wishes to sound a note of duty in this connection, duty of the members not to their pocket books, not only to their membership, but primarily to the public whose health it is their duty to conserve.

The unlicensed practitioner can only be put out of business if the doctors will act.

A CURRENT soap advertisement pictures the stork bringing a baby that looks to be about two years old, fully dressed, with a fine crop of blond hair neatly brushed and parted. How times have changed.

THE United States had in 1933 what was probably the best health record "of all times," according to a report of the Metropolitan Life Insurance Company. The signs, too, for 1934 are excellent, barring unforeseen epidemics. Influenza is not expected to visit us in extensive or virulent form, as we had a major visitation in 1932-1933.

An English schoolboy, writing an essay on "Doctors," said: "Doctors are very kind people. Sometimes they order the schools to close."

Correspondence

Anonymous letters will not be noticed. All communications must carry full name and address of the writer, but these are omitted on request.

To the Editor:

Permit me to congratulate the authors of the editorials in the January 15th issue of the Journal. They exhibit a philosophical insight and breadth of vision all too rare in our professional journals.

As a specialist may I comment particularly on your editorial on "The Certification of Specialists." In the main I am fully in accord with the views expressed concerning the present usefulness and the probable future importance of the work of the Examining Boards now functioning. Surely they have blazed a trail for the licensing of specialists which is of immense importance to both the profession and the public.

We should all, therefore, be interested in enhancing the usefulness of these Boards by making their certificates sought after by all who would aspire to a specialty. At the present time there are in this State many competent specialists who do not deem it worth the effort to attain a certificate. Then, too, there is not now available to the profession in general, and to the public, any ready means of identifying a certified specialist short of visiting his office and finding his certificate. To state these facts is to point to two very grave defects of the present system.

I believe both these faults may be easily remedied by giving publicity to the holding of a certificate. Furthermore this object may be readily attained in this State by attaching to the specialist's name in the State Medical Directory some abbreviated notation such as "Cert. Am. Bd. Oph.," etc., as the case may be. Can there be any valid objection to such a plan? Moreover, is it not likely that publicity of this sort would further the formation of examining boards in all specialties and that then no specialist worthy of the name would care to be listed in the Directory without the appropriate legend?

I feel so positive that I am right in this matter that I would appreciate your publishing this letter or embodying its views in a future editorial.

JOSEPH POPPER.

To the Editor:

I wish to express my pleasure and satisfaction in perusing the January numbers of the State Journal. The appearance of the Journal is certainly improved and the advertising material is nicely presented. The scientific articles are of excellent quality and all the Editorials thus far observed have been excellent reading for the rank and file of physicians throughout the State.

I was particularly impressed with the editorial in the second number which called attention to facts that can be forgotten in the uncertain affairs of to-day.

If this change in the direction and publication of the State Journal is a money saver, I should estimate this as the least important of its accomplishments.

DR. CHARLES H. GOODRICH

Society News

Committee on Legislation

Bulletin No. 3

Since the issuance of our last bulletin the following bills have been introduced:

Senate Int. No. 207—Mastick; Assembly Int. No. 248—Pratt, would amend the Vehicle and Traffic Law by increasing the fee for operator's license from \$1.00 to \$3.00 and for the renewal of license from 50c to \$2.00. Referred to the Internal Affairs Committee.

Every doctor should be interested in this amendment because of its adding an additional annual tax of \$1.50.

Senate Int. No. 235—Byrne, would add a new section to the Labor Law for bureau of industrial rehabilitation in the Labor Department in charge of a chief and nine investigators, bureau to operate clinics, each in charge of a physician with necessary assistants to give medical treatment to persons injured in industrial accidents and applying for workmen's compensation. Referred to the Labor Committee.

We are informed that this bill was prepared by the Department of Labor and that members of the Department have been talking about its provisions for some time. It would set up the Department of Labor as a treatment agency and with its salaried physicians very definitely compete with the general practitioner. In the light of our present information, we think this legislation should be opposed.

Senate Int. No. 257—Warner; Assembly Int. No. 279—Otto, would amend the Public Welfare Law relative to responsibility of public welfare districts for providing medical care by striking out "and for such persons otherwise able to maintain themselves." Referred to the Judiciary Committee.

You will recall that a bill similar to this was before the Legislature last year. It remained in committee in both Houses.

Senate Int. No. 280—Esquirol, would amend the Criminal Code by giving special sessions courts jurisdiction of offenses affecting public health. Referred to the Codes Committee.

We haven't been able to discuss this bill with Senator Esquirol, hence we are not in a position to comment upon it in this bulletin.

Senate Int. No. 297—D. T. O'Brien; Assembly Int. No. 324—Garnjost, would add a new section to the Insurance Law to exempt non-profit hospital service plans of a corporation organized under Membership Corporations Law so they may provide hospital care, with approval of insurance superintendent. Referred to the Insurance Committee.

The object of this legislation is to permit hospitals to conduct a form of insurance by selling membership which would entitle members to a certain amount of hospital service with no extra charge. The amendment would permit such organizations to operate under the supervision of the Insurance Department, but

without complying with all the conditions ordinarily required by the Department.

Senate Int. No. 304—Thompson; Assembly Int. No. 327—Hall, to amend the Public Health Law by requiring police to remove unidentified dead bodies to nearest general hospital maintained by county where an autopsy may be had unless objection is made by next of kin within 48 hours after death. Referred to the Health Committee.

Assembly Int. No. 264—Cohen, creates temporary commission to make a study and survey of administration of Workmen's Compensation Law and appropriating \$15,000. Referred to Ways and Means Committee.

Assembly Int. No. 289—Theodore, to amend the Workmen's Compensation Law by permitting injured employee to request employer to furnish medical attendance or to furnish attendance himself at expense of employer. Referred to the Labor Committee.

This is the free choice bill that Mr. Theodore had in last year.

Assembly Int. No. 353—Hamerman, would add new section to the Public Health Law prohibiting employment of domestic servants in first and second class cities not having a physician's certificate showing freedom from tuberculosis and any other contagious or communicable disease. Referred to the Health Committee.

It seems to us that this amendment is more exacting than is necessary. A person may have tuberculosis in a quiescent state, and so long as it remains that way, be perfectly harmless to associates. Our suggestion is that the examination is highly desirable and the prospective employer should be accurately informed as to the physical condition of the applicant, so that if there is no immediate danger of communicating the disease the employer should be permitted the privilege of hiring the applicant if he desires to do so. If all persons with syphilis, gonorrhea, and other communicable diseases are prevented from taking positions as servants regardless of the stage of their disease, it seems to us an unnecessary hardship will be imposed.

The local newspapers have announced for two days that an antivivisection bill has been introduced. The announcement is premature; no such bill has appeared as yet, but we shall be greatly surprised if one does not appear.

You will note above that the Legislature will be asked to appropriate \$15,000 to finance an official investigation of the manner in which the Workmen's Compensation Law is operating. There doesn't seem to us to be any need for this expenditure; two well-qualified committees have studied the situation in the last two years and the report of the second of these was submitted to Governor Lehman and published within the last month. You probably have a copy of the report. The Governor's committee is very eager to have its report recognized and asks that every County Society take some action with regard to it. It is hoped that the report can generally be accepted and that

suggestions will come to the Governor for amendments to the law in accordance with recommendations submitted by the committee. Will you take this matter up with the president and secretary of your County Society?

Are you keeping your legislators informed as to your reaction upon the bills which we have reported? Quite a number of chairmen are communicating with us regularly regarding the reports we are submitting, but we should be much happier if we could say that we are receiving communications from every chairman. Please give this matter your earnest attention and keep in touch with us and with your legislators.

A good many complaints have reached us recently regarding certain objectionable radio programs; namely, those of the Crazy Water Crystals Company, Father John's Medicine, and Mount Clemens Mineral Water. We are endeavoring to find a way to prevent their continuance, but we find it a very difficult matter. These people hold contracts with the national broadcasting companies, which claim they are not violating any law. These companies are purely commercial-minded and are not inclined to respect our Code of Ethics. If you have any suggestions as to how we might proceed more effectively, we shall be grateful to have them.

At the suggestion of the American "telegraphed to certain asking them to support the treatment only of veterans who have disabilities related to service.

We are planning a meeting of the county chairmen. Tentatively, Thursday, February 15th, has been selected as the day. The conference, of course, will be held in Albany. Will all of you who are chairmen please keep this date open.

P. S. Assembly Int. No. 364—Mr. Breen, the annual vivisection bill. This bill was introduced January 25, right after we had written the above bulletin. It is identical with the bill of last year.

COMMITTEE ON LEGISLATION:

Harry Aranow,
John J. Buettner,
Bernard B. Berkowitz,
B. Wallace Hamilton,
Edward E. Haley,

Bulletin No. 4, February 2, 1934

Since our last bulletin the following bills have been introduced:

Senate Int. No. 336—Hendel, to amend the Public Health Law by providing a child or person not vaccinated must be admitted into school in a city of 50,000 or more inhabitants, on recommendation of health or other board having jurisdiction. Referred to the Health Committee.

Mr. Hendel has introduced this bill by request of one of his constituents. He is not in sympathy with the bill and will not press it. We, of course, have filed our opposition and

will do what we can to prevent the bill from leaving committee.

Senate Int. No. 348—Baxter, would add a new section to the Penal Law making it a misdemeanor for a person wilfully to give a false police alarm or ask for police assistance through a false statement of fact or wilfully through any such false statement to ask for assistance from any funeral director, embalmer, doctor, or hospital or the aid of any ambulance. Referred to the Codes Committee.

Senate Int. No. 373—Crawford, would add a new section to the Penal Law, providing a hospital supported at public expense shall not charge any fee for medical, dental or pharmaceutical services while operating clinic to which public is invited. Referred to the Codes Committee.

Senate Int. No. 374—Crawford, would add a new section to the Public Welfare Law for central bureau of hospital clinics in each public welfare district to promulgate rules for persons applying for treatment in hospital clinics. Referred to the Judiciary Committee.

You will recognize that these latter two bills were before the Legislature last year. We approved them and a hearing was accorded the hospital dispensary bill. During the summer several committees of hospital representatives studied these questions and have prepared a report of their findings which they have presented to the New York County Society and we are told it was favorably received. Of course, we are heartily in accord with the principle of both bills and we shall approve them again this year.

Senate Int. No. 383—Wicks; Assembly Int. No. 450—Steingut, would extend to February 15, 1935 life of Temporary Emergency Relief Administration for unemployment relief and making other changes. Referred to the Finance Committee.

Senate Int. No. 427—Cilano; Assembly Int. No. 442—O'Mara, relative to emergency relief administration so as to permit hospital care and home relief for veterans. Referred to the Finance Committee.

Mr. Cilano had this bill last year. It includes veterans among those to receive home relief and hospital care from the county commissioner.

Senate Int. No. 450—H. L. O'Brien, to amend the Education Law to permit an osteopath to administer drugs or perform surgery, except certain operations, applicant for license to pass examination prescribed for physicians. Referred to the Education Committee.

This is the osteopathy bill which we have defeated in two preceding years. We shall need your hearty assistance in killing it again.

Senate Int. No. 462—McNaboe; Assembly Int. No. 489—Condon. This is a new hospital lien bill which does not include the physicians and nurses. Referred to the Judiciary Committee.

Of course, we shall lend our support to the first bill reported this year, in which claims of the physicians and nurses are recognized.

Assembly Int. No. 410—Murphy, would amend the Workmen's Compensation Law by providing compensation for all occupational diseases arising out of employment and relative to notice, information and penalty. Referred to the Labor Committee.

Another occupational disease bill which provides for an unlimited list and will be opposed by us as are the others similar to it now before the Legislature.

Assembly Int. No. 415—Dunkel, relative to the practice of pharmacy. Referred to the Education Committee.

This bill was prepared by the Pharmaceutical Association according to our information.

Assembly Int. No. 417—Dunkel, to amend the Education Law by providing package failing to bear statement of content of barbituric acid is misbranded and relative to use of poisonous or habit-forming drugs and chemicals. Referred to the Education Committee. A similar bill was before the Legislature last year, introduced by Mr. Gimbrone. A good deal of opposition was expressed to its advancement.

Assembly Int. No. 485—Breitenbach, to amend the Workmen's Compensation Law relative to occupational diseases so as to include in definition "dermatitis" any process involving direct contact with brick, cement, lime, concrete or mortar. Referred to the Labor Committee.

We haven't seen a copy of this bill as yet and, hence, are not in a position to make any comment.

Assembly Int. No. 507—Monahan, to amend the Labor Law, making 8 consecutive hours in any 24 a legal day's work for nurses in public hospitals or hospitals supported in whole or part by public funds. Referred to the Labor Committee.

Assembly Int. No. 520—Schwartz, would add a new section to the Penal Law making it a misdemeanor to sell drugs, medicines and

other pharmaceutical preparations including lotions not having affixed on bottle, box, vessel or package a label giving name and quantity of each ingredient. Referred to the Codes Committee.

ACTION ON BILLS

Assembly Int. No. 128—Condon, practice medicine, person pardoned; advanced to third reading.

Senate Int. No. 249—Mandelbaum, State Housing Law, providing for establishment, organization, operation and dissolution of municipal housing authorities. Has gone to the Governor.

We did not report this bill because we did not want to do so until we could read it. It does not affect the practice of medicine, but it may indirectly have a great effect upon public health conditions in our larger cities. It authorizes a community to create a housing authority with power to purchase houses in slum districts at their assessed value and convert the space into parks or rebuild it with a certain type of tenement house. The bill met little opposition; it was passed through both houses as an emergency measure and without doubt will receive the Governor's signature if it has not already done so.

It is important that you get in touch with members of the Senate Education Committee and place at once your objection to the osteopathy bill. The bill is identical with the one of last year and we shall base our opposition on the same grounds; namely, that the osteopaths have not studied pharmacy or materia medica; they have no knowledge of drugs; in fact, they have been trained to condemn drugs; and although the bill would seem to give them the use of but three drugs, it would really give them the use of three enormous groups of drugs, some of which are among the most powerful narcotics and poisons used by the physician.

We have received a number of inquiries concerning a 2 per cent sales tax that would apply to professional incomes as well as sales. No such bill has been introduced this year. Last year Senator Fearon had a 2 per cent sales tax bill which exempted the professions. During the summer there has been considerable agitation for the recommendation and passage of such a bill. The Council of Mayors and the realtors have endorsed the proposition and are endeavoring to create public sentiment in its favor. On the other hand, the Retail

Merchants' Association has been marshaling other groups in opposition to the proposition. If such bill is introduced we shall send you a copy as early as possible, in order that we may have your instructions.

We have definitely decided upon Tuesday February 13th, as the date for the conference of the County Chairmen. We were obliged to change from the 15th because of some other engagements. Will the chairmen therefore arrange their programs so that they can attend this important conference in Albany on Tuesday February 13th. Further instructions will be found in our next bulletin.

The "white book" has not yet been published, but it is important that you should communicate with members of the Education Committee in the Senate your opposition to the osteopathy bill and with members of the Senate Public Health Committee your opposition to the antivaccination bill. Members of those committees are

B. Wallace Hamilton
Edward E. Haley

Report of Executive Officer to the Executive Committee

Your Executive Officer begs leave to offer the following report for the Month of January.

The County Societies efforts to assist their with the various relieving agencies are at present Welfare commissioners, whether county city or town, are providing home relief for all indigents, and home relief embraces medical care. If the case method is employed by which physicians are authorized by the welfare commissioner 66 66 per cent of the their homes, the Temporary Emergency Relief Administration (TERA) refunds the welfare commissioners 66 66 per cent of the amount expended in providing the care. This

method obtains generally in the rural districts. In many of the larger cities, however, the welfare commissioner employs physicians on salary to care for the indigent and by this method forfeits the TERA refund. The welfare commissioners are also obliged to provide hospital care when it is needed. The budget that the TERA has for financing work relief is now supplementing the home relief budget while the Federal Government has taken over those employed on work relief under its new Civil Works Administration. Directors of the CWA have been instructed by the Federal Government to provide medical care for their employees by cooperating with the County Medical Societies. Lists of physicians wishing to treat injured workmen are being prepared by County Societies and submitted to the CWA directors. In many instances injured workmen are permitted to select from the list the physician they would like to have care for them. Physicians submit their bills through the director to the United States Employees' Compensation Commission and are permitted to make charges such as they would if privately treating persons in that same economic class. Another group Civil Works Service (CWS), includes persons who are employed by the state in assisting with CWA projects. These people are insured under the State Insurance Fund. On all projects financed by the state, as, for instance, highway construction, etc., the employees are insured by the state and carried with the State Fund.

In this connection it is interesting to know that the State Insurance Fund has sent to some CWA directors—probably to all—a letter advising them that if medical attention is needed for any CWS employees, certain named physicians are to be employed. When the physicians of Herkimer County, which was the first to report this action that the State Fund had taken, presented the CWA director a list of physicians willing to work for the United States Employees' Compensation Commission, they were told by the director that he had received instructions from the State Fund to employ only one of two named physicians. Obviously, neither the director nor the physicians were aware of the distinction between CWS and CWA for the State Fund can have nothing to do with CWA employees.

It is rather presumptuous for the State Insurance Fund to select physicians. It probably reasons that if the state carries the insurance and the law provides that the employer shall provide medical care, the State Fund being the insurance agent but, nevertheless, carrying the name "State," can assume the privilege of providing the medical care. It is rather disappointing to find that the State Insurance Fund is not willing to permit the injured to employ a physician of his own choice, a plan which is working very satisfactorily under the TERA and gives promise to work equally satisfactorily with the United States Employees' Compensation Commission. Efforts are made annually to have all industrial insurance in the state carried by the State Fund. Another such bill has been introduced this year. Another bill bearing upon this subject is before the Legislature, prepared by the Department of Labor, it is said, asking for authority for the Department to establish rehabilitation clinics throughout the state where

injured workmen may be treated and provided medical and nursing service.

A bill asking for an appropriation of \$15,000 to make an investigation of the Workmen's Compensation Law, has been reintroduced. It seems that there is no need for further study of this law, but an investigation of the motives of the State Department of Labor and the State Fund might be worth considering. This bill calls for the appointment of a certain number of Senators and Assemblymen and two persons to be appointed by the Governor. If there is any likelihood of the bill going through, it might be well for the Medical Society to have in mind one or two persons to be recommended to the Governor for his consideration as candidates for appointment to the commission.

Some pernicious legislation has appeared. The annual antivivisection bill has been introduced this year by an Assemblyman from Troy; the antivaccination bill which has been out for several years has been reintroduced; and we are assured that the osteopathy and chiropractic bills will be back. A brief of the chiropractic bill is being distributed.

Senator Crawford has reintroduced the hospital dispensary and central registration bureau bills of last year. The United Hospital Fund has had an amendment to the Insurance Law introduced which is intended to permit any membership corporation to procure hospital service for its members. This bill has been drafted in accordance with the recommendation made in the report of our Committee on the Costs of Medical Care. Your attention should be directed to the fact that the amendment does not limit the right to provide medical service to hospital corporations, but would permit any membership organization to make arrangements with any hospitals provided they are approved by the Department of Social Welfare, to provide such service, with only one condition, that is that the service shall be nonprofit bearing. A membership corporation is not able to make a profit and distribute it by dividends, but can create a large and well-paid executive staff, so that the creation of hospital membership groups need not necessarily be an undesirable undertaking. There is another angle to this matter that should be given some consideration and that is that there is nothing to prevent an individual hospital from creating a membership organization of its own and in this way hospitals could compete with one another for public support, and in competing they might conceivably reduce the membership fees below what would be the actual cost of the medical service to be provided. In this connection it may be interesting to learn that the Attorney General was recently asked by the Department of State to pass upon an application for incorporation by a group of New York people. He advised against granting them a certificate; his opinion follows:

"I have your letter of December 26th in which you enclose a proposed certificate of incorporation of Royal Sanitarium, Inc., the first two paragraphs of the statement of objects of which read as follows:

"(a) To erect, build, furnish, equip, establish, maintain, manage and operate buildings and institutions in the Borough of Manhattan City, County and State of New York for

the residence, boarding, nursing and lodging of private patients of outside physicians or surgeons for pecuniary profit.

"(b) To furnish the services of duly qualified registered nurses to such private patients but only by the expressed direction, authorization and under the immediate supervisory control and responsibility of such outside physicians and surgeons."

"You request my opinion as to whether the proposed certificate should be accepted for filing by your office.

"The proposed corporation is sought to be formed under the provisions of the Stock Corporation Law, Section 5 of which provides that a corporation may be formed under authority of that law 'for any lawful business purpose or purposes,' with certain exceptions not relevant here. It would seem to me that the term 'business purpose,' in its usual sense, denotes the commercial activities of persons engaged in profit-making enterprises, and that there is a very distinct cleavage between the activities carried on by persons engaged in business and persons practicing a profession. By the training, ability and peculiar skill required, nursing is today recognized as a profession. It does not seem to me that Article 2 of the Stock Corporation Law was intended to authorize a corporation to carry on a profession.

"It is well settled that a corporation may not be formed under Article 2 of the Stock Corporation Law to conduct a hospital (People v. Woodbury Dermatological Institute, 192 N. Y. 454; Opinions Attorney-General 1926, 192; 1928, 249; 1929, 121). This has been based upon the fact that a hospital, as usually constituted, has authority to engage physicians or surgeons for the treatment of its patients and would thus be engaged in the practice of medicine, contrary to law. In the instant case that authority is not sought but there is sought authority to employ duly qualified registered nurses and furnish their services to the patients of the Sanitarium. I think the distinction is insufficient between the powers of an ordinary hospital and the powers sought in the instant case to permit the filing of this certificate. I think, as was said in Godfrey v. Medical Society 177 App. Div. 684, that a dangerous precedent might be made which would lead to the opening of many quack sanitariums and Cure-All institutes under the guise of business corporations or registered trade names of individuals who are not licensed physicians."

"For these reasons, I think the proposed certificate of Royal Sanitarium, Inc., should be rejected."

In response to an urgent request from Dr. Cary, the chairman of the Legislative Committee of the American Medical Association, to Dr. Aranow, we sent telegrams to President Roosevelt, our two Senators and leading Representatives, advising them that our Legislative Committee approves of the President's proposition regarding veteran relief.

During the month communications have been received from physicians in different parts of the state asking whether something could not be done to prevent the Crazy Water Crystals Company from continuing its broadcasts. It recommends the crystals as a cure for almost every disease and does it openly

and brazenly in a manner in which it could never use the newspapers. Dr. Cramp of the A.M.A., advises that they have done all they can to prevent this company from committing this nuisance (J.A.M.A. March 11, 1933, vol 100, pages 760-761), but without avail. He says there is no way of censoring them. This information agrees with what we learned when we made inquiry in Rochester and Schenectady. The local companies told us that it was beyond them, they have to accept what is given them. We are told that recently the company has agreed to modify the character of its advertising.

Why So Few Physicians Form a Part of the Organization or Are Employed by National Health Organizations

This is one of the five problems submitted to the Committee on Public Relations by the last House of Delegates. Three of them were referred also to the Committees of the State Society on Public Health and Medical Economics, one of them to these Committees and to the counsel and one to these Committees and the Committee on Legislation. These problems have been given a good deal of study since last June. Conclusions will be formulated and published in the reports of these Committees. The first reference is, "Why so few physicians form a part of the organization or are employed by the National Health Organizations" The Public Relations Committee adopted the report of its Sub-Committee on this question. The question is a complex one. Practicing physicians have not interested themselves in these questions because they are usually so busy with their own private practices and so occupied with their own private worries that they are glad to think that some medical burdens have been shifted to other shoulders. The average practitioner of today received his training many years before the importance of preventive medicine was understood and before much teaching of it was done in our medical schools. The physician's heritage from the past still makes the average physician regard himself as an emergency man and it is difficult to interest him in anything except well developed pathology. A part of the responsibility for the attitude of physicians lies in National Health Organizations themselves. Any physician who would like to work with them has been alienated by the manner in which some are conducted. There should be closer cooperation between all health and welfare groups and the medical profession. No thinking person will deny that to bring about such a state of affairs is a great problem and its solution probably depends upon education. The medical profession is learning that it cannot alone handle the unsolved medicine of today and that there is need of coordinated effort on the part of all the groups which are working in public health. Out of such co-operative effort will come the betterment for which we all are striving and out of it too, will come the mutual understanding and respect which should prevail between all the groups that are working to raise man's living to a higher level. When this cooperative spirit has been developed then there will be no lack

of physicians to form a part of our National Health Organizations.

In the next issue of the STATE JOURNAL will appear a discussion of number two of the references of the House of Delegates to the Committee on Public Relations and in succeeding issues, a discussion of the other references when conclusions are reached

The Public Relations Committee
W. H. ROSS, Secretary

Civil Works Administration

Workmen's Compensation Department of the Civil Works Administration of New York City

—The Workmen's Compensation Department of the Civil Works Administration of New York City was organized by Mr. Howard S. Cullman, Deputy Administrator, with two basic objectives. The first of these was to furnish injured Civil Works Administration workers with competent medical care. The second was to provide a large-scale demonstration of an administrative technique in the handling of workmen's compensation cases free from abuses and rackets which have afflicted the compensation field elsewhere.

At the time the Department was being planned, the *Pool Report*, with its revelations and recommendations, had just been published. The New York Times, on January 1th, commented editorially on this report that "flagrant abuses are now a matter of common knowledge and understanding. Biased medical reports, incompetent medical treatment, and fee-splitting commercial clinics less clinical than commercial, padded and otherwise fraudulent claims—these are some of them"

Fully aware of these dangers, the Workmen's Compensation Department has endeavored to face the problem realistically. The question of weeding out corruption in this fundamentally humanitarian field would seem to narrow itself to two aspects first, personnel, second, procedures

On the personnel side, the Workmen's Compensation Department has endeavored to solve its problem by enlisting the services of outstanding experts whose wisdom and integrity were above reproach. The administrative organization which has been built up to date is headed by Miss Mabel Davies, Assistant of Superintendent of
and Dr. Samuel
ber of the medical
ment of Labor who
or the purpose by
Commissioner Andrews. A medical and surgical board was also formed, on a purely voluntary basis, consisting of a well-balanced group of distinguished physicians representing a widely diversified clinical and hospital experience and representatives of the County Medical Societies. On the board are Dr. Leopold Brahdry, Dr. Ralph Colp, Dr. Robert H. Kennedy, Dr. Marion Kenworthy, Dr. Eugene Pool, Dr. Theodore Sanders, Dr. David J. Kaliski and Dr. John J. Masterson. A medical and surgical advisory committee has also been appointed. Included in this group are Dr. Bernard Sachs, President of the New York Academy of Medicine, Dr. Maurice O. Magid, of the Bronx County Medical Society, Dr. John J. Masterson, of Kings, Dr. David J. Kaliski, of

New York, Dr. H. P. Mencken, of Queens, and Dr. Arthur S. Driscoll, of Richmond.

Believing that procedures in this field are to a very large extent a professional problem, and having full confidence in the personnel chosen to direct these policies, the formulation of a concrete plan has been left very largely in the hands of the responsible medical group.

One of the first acts of the medical and surgical board was to record its opinion that preliminary health examination should be done on all Civil Works Administration workers. The purpose of such examinations was not to reject applicants but to classify them according to their fitness for light or heavy work, or their need for hospital or social service care. It was strongly felt that such examinations were imperative to the well-being of workers who might suffer grave injuries as a result of labor beyond their physical capacity, and that the Government, as employer, was also assuming an unnecessary degree of responsibility for fictitious claims, avoidable accidents, and resulting costs. Delays due to various causes have made it impossible for such examinations to be made up to the present time but it remains the opinion of this Department that they should be made as soon as possible.

With approximately two hundred thousand workers employed by the Civil Works Administration at the present time, it was felt imperative that a plan be worked out which would assure these workers adequate care in the event of injury and at the same time safeguard them and the Government against medical or other racketeering. This problem was further complicated by the fact that some three thousand injuries had already occurred before the creation of this Department, that forms on these cases had been improperly filled out, and that both the administration and treatment of these cases had been proceeding in a wholly unplanned fashion; there was also a strong indication that monopolies in treatment and various medical specialties were already developing.

It was, therefore, necessary to adapt Federal Regulations to the needs of a large industrial center in such a way that first aid on projects would be provided, treatment at the hands of competent institutions or physicians

assured and such medical work and fees as might result distributed equitably on the basis of ability alone without regard to personalities or political affiliations.

The plan which will be put into operation at once will function as follows:

First: Physicians and surgeons registered with the Civil Works Administration will be employed to give first aid on projects primarily on a full-time basis, secondarily on a part-time basis.

Second: A preliminary panel of physicians and surgeons in each borough will be selected to whom cases requiring the services of an individual physician will be referred according to location, in rotation. This therapeutic panel will be composed of physicians chosen by the medical and surgical board from lists submitted by the various County Medical Societies. The dispensary clinical and hospital experience of the selected physicians will be taken into consideration as well as their general qualifications for compensation work.

Third: For hospitalization of injuries, federal, state, municipal and voluntary hospitals, in the order named, will be used to the fullest extent possible.

Fourth: An outstanding group of specialists will be designated in each borough to whom cases needing special care will be referred, in rotation. No monopoly of any specialized service will be given to any individual or group.

Fifth: Energetic accident and disease prevention measures will be undertaken through the first-aid units at the various projects in cooperation with the Engineers' Safety Division.

Sixth: Responsibility for reporting accidents will be centralized by designating one individual on each project or sub-project who will report accidents fully to the central office of the Workmen's Compensation Department.

Seventh: The physician on a given project will be authorized to refer to the central office for physical examination any worker who appears to be in a poor state of health or suffers from an obvious deformity.

HOWARD S. CULLMAN,
Deputy Administrator,
80 Eighth Avenue,
New York, N. Y.

A "Plain Tale from the Hills."—Out in the Rockies, in the he-man country, "where men are men," it looks as if the bracing mountain air has filled the medicine men with the old-time fighting spirit. Peacefully browsing through the medical exchanges we suddenly come across this startling editorial in the Wyoming Section of *Colorado Medicine*:

"There is at least one town in Wyoming where the doctors ought to have their heads bumped against the wall. Like a lot of spoiled kids, they fight, make ugly faces at each other, and talk like fools.

"The State Society ought to throw the whole

bunch out. They are educated and capable in their professional services to the people they serve, but they want to fight. Let them get together and go at it like men or shut up and behave. To go around like a bunch of old gossips is a disgrace to the profession and if they don't see the light, and that right soon, they will all be out in the cold. They can then settle their own malpractice suits or go to jail. Enough said."

Items like this put a "kick" into the usually tame task of exchange reading. Coming issues will be awaited with interest.

County News

Albany

Howard Eaton Lomax, Graduate of the Albany Medical College 1892. Member and past President of the Medical Society of the County of Albany. Formerly lecturer in Anatomy at the Albany Medical College. Instructor and Director National Training School for Certified Nurses. Died January 11, 1934 Age 66, from coronary thrombosis.

Nassau

At a meeting of the Medical Society of the County of Nassau, held on January 30th, 1934, the following resolutions were unanimously adopted:

RESOLVED, that the following statement be adopted by the Medical Society of the County of Nassau as representing the attitude of the organized medical profession of the County.

"The Federal and State authorities in the handling of medical care of injured persons have shown an increasing tendency to ignore the economic and professional rights of the physicians. The State authorities are demanding that medical care be given at fees which are less, in many cases, than the cash outlay by the physician and which at best do not give sufficient return to meet the normal overhead expense of the physician.

The Civil Works Administration of the Federal Relief Administration is evidencing a tendency to ignore the practicing physician except as he may apply for relief himself, under which conditions he would be paid only for working in public clinics.

"The State Workmen's Compensation Law provides in Paragraph 13 that fees and other charges shall be such as prevail in the same community for similar treatment of injured persons of like standard of life. In accordance with this law injured workmen in the employ of CWA have been cared for by our hospitals and by our physicians at standard minimum rates, but regulations dated January 23, 1934, addressed to all doctors and hospitals and mailed generally throughout Nassau County by the Nassau County CWA and Emergency Work Bureau provide that injured employees requiring hospital care shall receive general surgical care by the house staff of the institution, and further provides a fee schedule for such items as x-ray examinations which fee schedule is grossly inadequate, representing in many instances only a fraction of the actual cost of such examination.

"It is therefore the sense of this Society that any hospital treating such injured workmen for such inadequate compensation is thereby placed in direct and unfair competition with the members of its medical staff and it is further the sense of this Society that our State and National medical organizations should take vigorous action to effect a repeal of the many discriminatory regulations governing medical care and to secure the recognition by the Federal and State authorities of the principle that medical care is a necessity of life and should be provided when needed

through existing channels and be paid for at current minimum rates, and that in the meantime the local County officials be appealed to for assistance in so modifying the existing regulations as to make it possible for sick and injured clients of the various welfare organizations of the County to receive adequate medical care at fees which do not represent a financial loss upon the physician," and be it further

"RESOLVED, that copies of these regulations be sent to the New York State Journal of Medicine and to the Journal of the American Medical Association with the request that it be published, and further that copies be sent to the Board of Supervisors of the County of Nassau, the County welfare administrators, the President and Superintendents of the hospitals of the County, the Secretary of the American Medical Association and the Executive Committee of the New York State Medical Society.

General

Scientific Proceedings—Dr. Russell M. Wilder, Rochester, Minn., discussed the "Role of the Parathyroids in Health and Disease" before the Bronx County Medical Society.—Dr. Louis Fischer addressed the New York Society of Orthodontists, on "Interrelationships Between Orthodontia and Pediatrics"—Dr. Karen Horney, Chicago, among others, addressed the New York Neurological Society in a joint meeting with the section of neurology and psychiatry of the New York Academy of Medicine, on "Concepts and Misconceptions about the Principles of the Psychoanalytic Method"—Among speakers who addressed the Society for Experimental Biology and Medicine, were Dr. Sidney D. Kramer and M. Schaeffer, on "Experimental Poliomyelitis; Active Mixtures of the Tissue Culture of Encephalitis by Protection Test," and L. N. Ellis, Ph.D., "Experimental Evidence of an additional Substance Essential to Mammalian Nutrition." Drs. Soma Weiss, Boston, and Hugo Roesler, Philadelphia, addressed the committee on cardiac clinics of the heart committee of the New York Tuberculosis and Health Association at a meeting of the New York Academy of Medicine, on the "The Role of the Precipitin Aspects of Cardiovascular Disease," respectively.—Dr. Leonard G. Rowntree, Philadelphia, addressed the Medical Society of the County of Kings, on "Recent Advances in our Knowledge of Endocrine Diseases," and Dr. John L. Bauer delivered his inaugural address as president of the society, on "Medical Problems."—Dr. Louise D. Larimore and Walter C. A. Steffen, among others, addressed the Queensboro Surgical Society, on "Carcinoma of the Breast Pathology and Review of Cases" and "Congenital Pyloric Stenosis," respectively.—Dr. Russell L. Cecil delivered an afternoon lecture before the Medical Society of the County of Queens, Forest Hills, on rheumatic fever.

Medicolegal

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

CONTRACTS—AGREEMENTS BETWEEN PHYSICIANS LIMITING PRACTICE

Frequently doctors have made agreements with other members of their profession to refrain from the practice of medicine in a particular locality, and from such contracts a number of interesting court rulings have resulted.

A few months ago a high Court was called upon to test out the validity of such a restraint dealing with a contract restricting a certain doctor's practice of medicine in Chicago. Two physicians, Dr. S. and Dr. B., had been engaged in practice for some time under a partnership agreement. Advances had been made to Dr. B. in excess of his share of the partnership funds. Dr. S. became ill and inactive in practice and it was agreed that the partnership should be dissolved. A contract was therefore entered into between the two doctors whereby Dr. B. was to pay Dr. S. the sum of \$7,500—payable \$3,000 in cash and the balance within two years. Dr. B. was also to pay to his former partner the additional sums of \$125 every month for two years and \$100 every month thereafter for the balance of the life of Dr. S. In consideration of the winding-up of the partnership and of the premises, the following clause was included in the contract:

"It is specifically understood and agreed that Dr. S. agrees not to engage in the practice of medicine independently of Dr. B. in Chicago, and that when he returns to active practice with Dr. B. additional compensation shall be mutually agreed to."

After some months Dr. S. instituted a lawsuit against Dr. B. based upon the alleged failure of his former partner to make the monthly payments under the agreement. The defendant claimed in defense of the case that the contract was void, and unenforceable, asserting that it was against public policy because it restrained a doctor from practicing his profession in Chicago for an unlimited time. The trial court, however, gave judgment for the plaintiff. An appeal was taken and the judgment was affirmed by the Appellate Court which thereby sustained the validity of the contract. In ruling that the restraints which Dr. S. had assumed under the contract were valid the Court said:

"The question whether the restriction upon the right of Dr. S. to practice his profession, as made by the contract, is unreasonable is one of law, to be determined under the particular facts of this case. It is to be noted that the

reason Dr. S. retired from the practice of his profession was, as recited in the contract, because of his inactivity due to a protracted illness; that by the contract he is not restrained from practicing his profession at any place in the state outside the city of Chicago; and that as to the city of Chicago the restraint upon Dr. S. is not total but only that he will not practice his profession independently of Dr. B. The contract is supported by a valuable consideration, the restraint imposed is limited or partial, and we do not regard the restraint to be greater than is reasonably necessary to protect the contract rights of Dr. B. or to be against public policy."

In a somewhat different situation recently decided in another of the Midwestern States, injunctive relief was granted by the Court to enforce a similar contract. In that case the plaintiff was a physician who had for many years engaged in his profession in the City of A. He made an agreement with a younger man who had been licensed to practice for only about a year whereby the older man undertook to furnish offices to be shared by the two men in a joint practice. The younger man was to pay over to the older 30 per cent of his fees. The venture was to last for one year, and it was further contracted between them that as a partial consideration for the arrangement, the younger man agreed that if at the end of the year he should sever relations with the older man, he would not for a period of three years thereafter engage in the practice of medicine in the city of A. in opposition to the other. The two men worked together for a year, severed relations, and promptly the younger man opened an office in the same town. The older man sued to enjoin the younger from so practicing.

The Appellate Court in that case sustained the plaintiff's right to the relief he sought, and said in its opinion:

"The appellant, a young man and comparatively inexperienced practitioner, with no previous residence in the City of A., was, under the contract taken into the offices of the appellee, an old and established practitioner. It inevitably followed that the appellant became acquainted with the patients of the appellee and was in such a situation that it is quite reasonable to expect that in the course of time some of them might prefer the services of the appellant. To permit the appellant to

leave the offices of the appellee and establish a competing office in the same town in direct derogation of the terms and provision of the written contract, and require the appellee to resort to a court of law to prove the specific damages that he might suffer by the loss of patients who sought the services of the appellant in preference to those of the appellee and deny equitable relief would be to place a very serious limitation upon the general broad and plenary powers that rest in a court of chancery."

These cases seem to be in accord with the rule laid down by the Courts of this State years ago. The principal case upon the subject in New York seems to be one in which years ago a doctor desirous of practicing in a certain community bought from another practitioner a house and lot, "some office furniture, and his ride and good will." The physician so selling his office agreed in consideration for the sale never to practice medicine within the same County, one of the upstate counties. Within four years, however, he did return to the County to practice, and suit was started to enjoin him from so doing. In his defense he claimed that the contract was void on the grounds that it was (a) unreasonable, (b) in restraint of trade, and (c) against public policy. In that case the Court said in upholding the terms of the contract:

"That an agreement in general restraint of trade is utterly void was decided at least a century and a half ago and has been the unquestionable law ever since, but the very case which settled this doctrine irrevocably, also held that a promise to restrain one's self from trading in a particular place or within a limited district, if made upon reasonable consideration, is good. The only inquiries to be made, therefore, to determine the validity of a contract restraining the exercise of a trade or profession, are, first, whether the restraint is partial, second, whether it is upon an adequate or merely colorable consideration; and third, whether it is reasonable. Without attempting to exhaust the learning upon this topic with which the books abound I propose to examine very briefly the contract in this case, in view of these principles and by the light of a few authorities bearing upon them. And in the first place the restraint imposed in this case is doubtless a partial one. A general restraint is in England defined to be one which forbids a person from

employing his talents, industry or capital in any undertaking within the Kingdom; but individual interest and general convenience render engagements not to carry on a trade or act in a profession in a particular place proper. Such special restraints as to places and districts of country have been frequently upheld in England and in this country, as we shall see more particularly when we come to the consideration of the reasonableness of the restraints which are sought to be upheld. In this country, therefore, it may perhaps safely be assumed that, by analogy, any restraint that embraced within its scope the territory of the State would be general and therefore void; while a local and limited territorial restraint is partial, and if not unreasonable is valid . . .

"I am unable to say that the County of O. either as to extent of territory or the amount of its population, constitutes so wide a field as to make the restriction which the defendant imposed upon himself by his contract in this case an unreasonable one. A fair consideration was paid by the plaintiff for the privilege purchased by him and I cannot say that the restraint is larger or wider than his protection may possibly require."

Among other such contracts that have been passed upon and sustained as enforceable by the Courts of New York are the following:

1. A contract selling a piece of real estate, and the vendor's practice as a physician and surgeon in a certain village, in connection with which the vendor agreed not to locate himself and practice within six miles of said village for ten years, with a provision that if he did so locate or practice he would pay to the purchaser \$500 on demand for every month he practiced in violation of the agreement.

2. An agreement for the sale to a former partner of office equipment, in connection with which the vendor bound himself to pay \$500 as liquidated damages if he should within five years' practice in the village or town in which the office was located.

3. A contract made between two dentists whereby one purchased the good will and business of the other and obtained his agreement not to reenter for five years the practice of dentistry within the territory bounded by the Harlem River on the North, Seventieth Street on the South, the East River on the East and the North River on the West.

Books Reviewed

The History and Epidemiology of Syphilis.—By William Allen Pusey, M.D. Octavo of 113 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1933. Cloth, \$2.00.

This book gives in a very comprehensive manner all the known facts concerning the history of Syphilis and reaches the conclusion that Syphilis originated in the new world and was carried back to Europe by Columbus. After brief biographical sketches of the outstanding workers and their contributions in this field of medicine, the author devotes a chapter to the epidemiology of Syphilis and states that the number of new cases of Syphilis per year is about stationary (in the United States, at least) and that very little is being accomplished toward its ultimate eradication. Altogether this volume is a fitting companion to Dr. Pusey's earlier work on "The History of Dermatology." It is a well worth while addition to any physician's library.

JOHN C. GRAHAM.

Physical Chemistry of Living Tissues and Life Processes.—As Studied by Artificial Imitation of Their Single Phases. By R. Beutner, M.D. Octavo of 337 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1933. Cloth, \$5.00.

The title of this book is interesting, and stimulates the hope that the author has gathered into a small place much of the knowledge concerning the basic principles of chemical activity in living matter. The hope is fully justified, and in an understandable way to anyone with even a modern knowledge of chemistry. All physicians interested in the chemistry of the body will find helpful information clearly presented.

The medical books of the future will contain much data of the type mentioned in this book, and plans of treatment will be instituted to restore disordered chemical reactions to their normal status. The foreground of this method is given in this work, and some of the mystery that surrounds the actions and reactions of living matter is clearly dispelled by the author.

It is impossible to have a thorough appreciation of sickness today without much of the knowledge contained in this book, and the reviewer hopes that in the future many similar ones will be published.

J. ARTHUR BUCHANAN.

Handbuch der Allgemeinen Hämatologie.—Band II, Hälfte I. Herausgegeben von Dr. Hans Hirschfeld and Dr. Anton Hittmair. Large Octavo of 700 pages, illustrated. Berlin, Urban & Schwarzenberg, 1933. Paper RM. 50.

As the editors state, this "Hand Book of General Hematology," of which the present part is the first half of the second volume, is devoted to the "technic of methods of investigation."

They have purposely omitted chemical, chemical-physical, physical and serological methods, to avoid consuming too much space and adding too much to the cost of the book.

There are twenty-three topics, treated by eleven different contributors; seven hundred pages of text and two hundred and sixty-nine illustrations. Space prohibits more than a very general review of what is really a massive work on a rapidly growing subject. The book is well illustrated and teeming with methods, old and new. For laboratories and those aiming to specialize on hematology, the work is valuable as a practical guide to technic and a work of reference; for casual workers on the blood it is too exhaustive. It should be in all laboratories and A-Grade Hospitals.

J. M. VAN COTT.

The Diseases of Infants and Children.—By J. P. Crozer Griffiths, M.D., and A. Graeme Mitchell, M.D. Octavo of 1155 pages, illustrated. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$10.00.

While this is the third edition of the Diseases of Infants and Children, and the construction of the book is much the same as in previous editions, the limitation to one volume with the elimination and additions necessary for this step, have really resulted in a new work. We believe that the purpose has been well fulfilled in that it is a text-book suitable for undergraduates and for physicians especially interested in pediatric subjects.

The printing and the paper are good which make for easy reading, and the illustrations are above the average. About 19 colored plates increase the interest.

Most of the subjects are brought up to date, but the treatment of chorea makes no mention of the newer shock methods such as nirvanol and typhoid vaccine.

It is a satisfying book to refer to, and is well worth a place on the shelf of the physician who deals with children.

ARCHIBALD D. SMITH.

Le Nystagmus Vestibulaire et les Reactions de Mouvements.—By R. Claué. 12mo. of 64 pages, illustrated. Paris, Nobert Maloine, 1933.

Read before the Section on Medicine at the Annual Meeting of the Medical Society of the State of New York, at New York City, April 4, 1933.

Vestibular tests seem to play an obscure role in the routine work of most ear specialists. This may in part be attributed to the fact that we have adopted too many methods without concentrating on a particular standardized procedure. As to the difficulties entailed in each of these tests the otologist is well familiar.

This little book (in French) attacks the rotary test as unreliable because it excites both labyrinths, is subject to wide variations, and because it cannot be tried out on a sick patient.

The author focusses his attention, however, on one test—the Caloric Test—which he describes in simple convincing terms, and by means of schematic drawings discusses its important practical applications.

EMANUEL KRIMSKY.

SURGERY ON THE PATIENT WITH DIABETES MELLITUS

By BEVERLY CHEW SMITH, M.D.

Assistant Visiting Surgeon, Presbyterian Hospital, New York City

Read at the annual meeting of the Medical Society of the State of New York, New York, N. Y. April 5 1933

The title of this paper presupposes the established diagnosis of diabetes mellitus. This diagnosis is frequently made by routine urinalysis in patients ignorant of the presence of the disease. Occasionally, multiple urinalyses are necessary to discover glycosuria, because patients with a moderate hyperglycemia may not constantly show glucose in their urine. If a wound fails to heal properly with adequate surgical treatment, diabetes should be suspected, and if urine is negative for glucose, a fasting blood sugar test should be done to determine a hyperglycemia.

The medical treatment of diabetes has become so proficient, that a diabetic can be treated surgically almost as a nondiabetic patient. This statement has been made before, and is largely true, but there are certain details in the treatment of surgical diabetics which must be meticulously executed to secure the same results one would expect in nondiabetics, with a similar lesion. Inflammatory lesions in diabetes are aggravated by hyperglycemia. Infection diminishes diabetics' carbohydrate tolerance. Their tissues are more susceptible to dressing trauma. Inflammatory lesions are best healed by adequate drainage and reduction of hyperglycemia. The clinical course following guillotine amputations of gangrenous extremities in septic diabetics vividly illustrates this statement. Diabetics are particularly susceptible to infections in their toes and feet following the cutting of corns and calluses. These injuries often lead to gangrene, with or without infection, depending upon the amount of arterial blood supply. The sequence of infections from closed spaces of digits such as cellulitis, abscesses, thrombophlebitis, arterial thrombosis, suppurative arthritis, osteomyelitis, and suppurative tenosynovitis, should be anticipated and clearly comprehended.

The separation of patients from infection in parts which need not, or cannot be imputed, necessitates an understanding of anatomical spaces, principles of adequate and maintained surgical drainage and a realization of the difficulties of securing such drainage.

At the Presbyterian Hospital, in 1930, the Director of Surgery, Dr. Allen O. Whipple, set aside eight beds for the treatment of surgical diabetic patients. During the past three years we have treated 172 surgical diabetics in these eight beds.

TABLE I*

	Total medical and surgical admissions	Surgical diabetic admissions	Total surgical admissions	Total medical and surgical admissions
1930	315	59 (18.7%)	4800 (1.2%)	6479 (0.9%)

* Gynecology and other specialties are not included in the total admission figures.

The concentration of surgical diabetic admissions on a service has enabled us to decrease the mortality in this group. Where we previously imputed above the knee for arteriosclerotic diabetic gangrene, we now impute below the knee. The results have taught us a continuation of conservatism as compared to more radical attitudes in other clinics. The mortality in 50 diabetic amputations of the leg and thigh from 1916 to 1927 was 46 per cent. The mortality in 29 amputations in 1930, 1931, and 1932 was 37.9 per cent. For the past three years on the Second Surgical Division at Presbyterian Hospital, there has not been an amputation through the thigh for diabetic arteriosclerotic gangrene except for gas bacillus infection. I believe that thigh amputations for gangrene in diabetics with arteriosclerosis is in a great many instances more radical than is necessary. If amputation is properly performed at the site of election below the knee, and care exercised

with drainage, dressings, and medical supervision, there should be fewer extremities needlessly sacrificed through the thigh.

In the routine care of diabetics, we attempt to simplify the necessary laboratory observations. If urine shows glucose, it is examined for diacetic acid with ferric chloride. If this is negative, CO₂ combining power of the plasma is not done unless there is clinical suspicion of acidosis. If the ferric chloride is positive, we do a CO₂. Ferric chloride reaction may be negative in the urine of dehydrated diabetics who show clinical signs of acidosis, and yet become positive if sufficient fluid is given to wash acid bodies out of the blood and tissues.

Should impending acidosis be noted, treatment is immediately begun by a medical attending physician. It consists briefly in the administration of orange juice, using 100 c.c. as equivalent to 10 gm. of glucose, and if patients are unable to drink fluids, glucose is administered by clysis or intravenously. Insulin, ($\frac{1}{2}$ unit per gram of glucose) is given fifteen minutes before, and fifteen minutes after clyses or infusions. Voided or catheterized specimens are examined every one to two hours. Cases of severe acidosis or coma receive larger doses of insulin for each gram of glucose. Normal saline is administered by clysis or intravenously to combat dehydration without placing too great a burden on the circulatory system. In elderly diabetics, because of arteriosclerosis and myocarditis, about 2,500 c.c. in twenty-four hours is near the limit of safety. In younger patients with unimpaired vascular system, it may be raised to 6,000 to 8,000 c.c. in twenty-four hours.

We prefer not to give insulin intravenously unless it becomes necessary for the prevention of coma. Glucose given with it is excreted faster than insulin is utilized. The concentration of insulin in the blood and tissues may therefore be accumulative and produce shock.

The House Staff is instructed to watch for symptoms of insulin shock. If there is suspicion of it, we insist upon an immediate blood sugar test, and either orange juice by mouth, or 5 or 10 per cent of glucose is given intravenously. Diabetics are so prone to cardiac attacks, with symptoms simulating insulin shock, that the true condition may not be determined until the blood sugar is known. It is safer to produce temporary hyperglycemia than to allow patient to sink into insulin shock.

For treatment of glycosuria and regulation of insulin, we rely at first more upon urinalysis than upon blood sugar determinations. Each

voiding is examined for glucose. Ten units of insulin are given for a heavy reduction, and 5 units for a slight reduction of Benedict solution. A standing order of insulin may be further necessary in one, two, or three doses. A blood sugar test should be done when the urine becomes negative or when it does not become negative after a period of treatment, when there is a rise of temperature, a spread of a localized infection, or a maintained pyrexia. Conversely, an increased urinary or blood sugar indicates a spread of any existing infection.

WE DO NOT STARVE PATIENTS.—Diets are simplified into three types as follows:

(1)	150 gm. of carbohydrate	75 gm. of protein
	100 gm. of fat (for undernourished patients)	
(2)	100 gm. of carbohydrate	60 gm. of protein
	50 gm. of fat (for the average patient)	
(3)	50 gm. of carbohydrate	50 gm. of protein
	50 gm. of fat (for obese patients)	

Thus equipped with a urinalysis outfit, dietary list of three diets, and insulin, and an occasional blood sugar test, we believe that the average surgical diabetic can be successfully cared for. In cases of severe acidosis, however, complete laboratory facilities are useful.

The ideal toward which we strive in the treatment of surgical diabetics is the maintenance of a normal blood sugar regardless of the paucity of diet, or the amount of insulin. Like all ideals, this one is not always attainable because of infection which in all cases enhances the severity of the diabetes. Observation of diabetic wounds indicates that they heal better in the presence of a normal blood sugar. This necessitates daily or several times daily observation by the medical attendant.

I vividly recall surgical cases, whose wounds were satisfactorily healing with their blood sugar controlled by insulin and diet, who, when referred back to their medical doctor, or even to a medical service in a hospital, have had their blood sugar raised in an effort to increase their nutrition by giving a high CO H diet with a moderate increase of their insulin with the result that a hyperglycemia occurred, and their wounds either suppurated more, or became sluggish to the extent of serious retardation of their healing.

It is most comforting to have the advice of a medical confrere in estimating the cardiovascular renal competency of surgical diabetics. It is frequently difficult to discover and evaluate existing pathology of the myocardium, coronary vessels, systemic blood vessels, and kidneys. In spite of laboratory examinations

including blood chemistry, renal tests, electrocardiographs, x-rays and the like, we have so often seen unexpected serious cardiac complications following the extra burden of operation in the presence of inflammation or from the operative trauma itself, that we feel a guarded prognosis is particularly advisable in elderly or long existent diabetic cases.

Routine eye examinations have revealed diabetic retinitis in every case of diabetic gangrene of the toes or feet.

Diabetics are susceptible to any surgical disease that nondiabetics might acquire. They are particularly susceptible to infections in the lower extremities (terminating in gangrene), and in the skin (terminating in carbuncles). A surgically supervised foot clinic in charge of a competent pediatricist has been a valuable adjunct to the Surgical Diabetic Clinic for prophylactic treatment of corns and calluses.

The absence of osteomyelitis in diabetics, except in digits, has been noticeable in our cases. This is probably coincident.

Carcinomata of the stomach, breast, colon and rectum have been encountered. In these cases, diabetes has added tremendously to the mortality of surgical therapy.

In appendicitis with localized peritonitis, diabetes has not been the serious factor that it has been in the more advanced cases of peritonitis. Often we have found it necessary to delay surgery in the presence of extensive peritonitis to treat the accompanying acidosis. Surgical delay has not been so necessary in cases of appendicitis with localized peritonitis. A clysis with insulin either before, or after, or both, usually suffices.

We have seen so many acute and chronic cholecystitis cases with and without stones in the gallbladder and common duct pass successfully through operative procedures and convalescence, that we expect their recovery as in nondiabetics, provided cardiovascular complications do not intervene.

In acute cholecystitis, the diabetics' glucose tolerance is greatly diminished and we are inclined to do cholecystostomies rather than cholecystectomies. Diabetes is easier controlled if acute gallbladders are drained and not removed. Later they may be removed, if necessary, in the absence of acute infection. We are more inclined to operate on acute gallbladders in diabetics earlier than we do in nondiabetics.

We believe that adequate drainage is advisable in these cases, bearing in mind that

too tight an abdominal wall closure about the drains may defeat our purpose.

Infections of the pleura and lung abscesses have been amenable to surgical drainage with appropriate treatment of their diabetes.

Paronychia, abrasions, and slight puncture wounds may be harbingers of a prolonged hospitalization, amputation, or may even lead to death. The best treatment of such extremity lesions is, first, their prophylaxis, and secondly, adequate surgical treatment immediately following their inception.

It is dangerous to amputate toes when the dorsalis pedis artery is not palpable. However, if there is evidence of a generous collateral circulation in the foot and toes as shown by high surface temperature readings, toe amputations may be done, but the site often will not heal, and sepsis may develop.

Many clinics teach that it is unwise to amputate through the leg when the popliteal artery is not palpable. I have often amputated through the leg when I have been unable to feel the popliteal. In some cases I had primary union. In others where the stumps were left open, the healing was slow and had to be supplemented by either Thiersch or pinch grafts. In no case was reamputation through the thigh necessary because of gangrene of the leg stump. In 2 cases gas bacillus infections required thigh reamputations. Both of these cases died.

It is difficult to palpate the popliteal artery. I do so by rolling it laterally against the lateral head of the gastrocnemius muscle in the popliteal space with the knee slightly flexed. I have often noted spurting from a divided popliteal artery that I could not palpate before amputation.

Oscillometric readings indicating pulsation in peripheral vessels and surface temperatures as determined with a dermaterm indicating collateral circulation, have helped in determining the level at which the blood supply could maintain a viable stump. I have amputated through the junction of the lower and middle third of the leg where there was practically no bleeding from the anterior and posterior tibial, or peroneal arteries, and have had union. The surface temperatures at the amputation site were close to normal (30.5° C.). These stumps have required longer to heal than tissues with a better blood supply, but they have remained healed during the one to three years they have been followed up.

Since 1930, I have used a technic which I developed and which will be published in *The*

Archives of Surgery under the title of "An Amputation Through the Lower Third of the Leg in Diabetic and Arteriosclerotic Gangrene." This operation embodies the minimal trauma to existing collateral circulation, excision of the bones from the investing muscles, and a guillotine of the soft parts at a sufficient distance from the bone ends, to leave a stump of tissue 2 to 3 inches long, covering the bones after shrinkage has taken place.

ANESTHESIA

Ether is not used because it either produces or exacerbates acidosis in diabetics. Spinal anesthesia is frequently used in abdominal work and only occasionally in amputations. We prefer a spinal puncture between the third and fourth lumbar vertebrae to collect 2 to 3 c.c. of spinal fluid in a vial containing 100 to 200 mg. of novocaine, dissolving the drug in the spinal fluid, and slowly reintroducing the solution in the spinal canal. In hypertension cases the fall of blood pressure may be so great that a suppression of urine may ensue. Fifty milligrams of ephedrine intramuscularly one-half hour before or at the time spinal anesthesia is given will usually maintain blood pressure. Other complications following spinal anesthesia are: Circulatory collapse of undetermined origin, persistent headaches, inability to void, transient paralyses and pulmonary complications. These, however, may follow its use in non-diabetics, but have occurred more frequently in the diabetic as compared to the nondiabetic group. We do not feel justified in using spinal anesthesia for toe or leg amputations unless pulmonary complications contra-indicate a short nitrous oxide-oxygen anesthesia. Spinal anesthesia is particularly useful in intra-abdominal surgery unless more than one to one and one-half hours is needed to complete the procedure. The relaxation and exposure that it permits often materially shorten the operation.

Ethylene has not been used at the Presbyterian Hospital in any case for the past five years because of its explosive dangers.

Infiltration novocaine is useful in non-inflammatory lesions. In the presence of infection it is not used unless there are contra-indications to a general anesthetic. I have occasionally used it for leg amputations in cases with acute pulmonary complications.

Avertin is not used in diabetics because of its depressing effect on blood pressure. It has not been shown to have any direct effect upon diabetes.

Nitrous oxide and oxygen is the anesthetic of choice in our hands for amputation of toes, legs, thighs, incisions and drainage of infected parts, breast operations, plastic procedures, and to supplement spinal.

An analysis of the 59 surgical diabetic admissions to Presbyterian Hospital in 1930 revealed the following. They represented fifteen nationalities; 42 cases were in the sixth and seventh decades, 16 knew they had diabetes from one to five years, 14, five to ten years, 8 ten to fifteen years, 3, fifteen to twenty years. Fourteen were uncertain as to the duration of their diabetes.

Duration of present illnesses varied from two days in a few cases to two years in 4 cases. In 15 cases it was two to five months.

Thirteen and one-half per cent gave a family history of diabetes. Thirty per cent did not know of the presence or absence of this disease in their family. Fifty-six per cent denied its presence in their family.

That arteriosclerosis associated with diabetes is not always accompanied by hypertension is shown by the fact that the systolic blood pressure in 27 was between 100 and 150. In 17, between 150 and 180, and in only 12 was it between 180 and 210.

Sixteen per cent had a blood urea above normal upon admission (*i.e.*, above 0.4 gm. per liter).

No surgical case was admitted in coma, but several showed severe acidosis. Thirty-five patients had a blood sugar between 2 and 3 gm. per liter preoperatively. Forty-six had a recorded blood sugar below 2 gm. per liter on discharge. Blood cultures were taken nine times. Two were positive, one grew a non-hemolytic streptococcus, the other a hemolytic *Staphylococcus aureus*. Both these patients died. Thirty-three per cent of the cases showed x-ray evidence of calcification in their peripheral vessels.

There were 7 hospital deaths, a hospital mortality of 11.8 per cent. Five others died within two years following their discharge from complications of diabetes.

These figures vividly illustrate the futility of statistics, as in 1930 and 1931, with a mortality of 25 per cent in the leg amputation group, we certainly did not encounter as severe or as frequent complications as we did in 1932 with a mortality of 62.5 per cent.

Because of our experience in 1932 with such a high evidence of gas bacillus infections, we now routinely culture all open lesions aerobically and anaerobically before any operation, so as to know the bacteriology we are

dealing with. If gas forming bacilli are present, we give a prophylactic dose of polyvalent serum (Lederle) before operation and treat either the local wound until gas bacilli can no longer be recovered and then proceed with a leg amputation, leaving the stump open and dakinizing it freely, or else proceed immediately with a thigh amputation and leave the stump entirely open and dakinize it.

A black dry gangrenous digit may harbor at its line of demarcation either a streptococcus, which does or does not form gas or another gas forming organism which at any given moment, usually associated with some mild trauma, may overwhelm its host and produce a septicemia.

TABLE II

1930			
			25 per cent
			50 per cent
			27.2 per cent
Two deaths following amputation through leg were due to sepsis. The death following the Griggs Stokes occurred in a patient 72 years old from pneumonia cerebral thrombosis, decubitus cystitis and pulmonary embolus.			
1931			
Amputation through leg	3	1	Mortality 25 per cent
Amputation through thigh	0		
Griggs Stokes	0		
Total amputations—4	3	1	Hospital mortality 25 per cent
1932			
			62.5 per cent
			33 1/3 per cent
			mortality
			50 per cent
The five deaths following amputations through the leg were due to sepsis. One case senility and pneumonia. Three cases gas bacillus infection. The deaths following thigh amputations were from coronary occlusion and gas bacillus infection.			

In 50 surgical diabetic amputations between 1916 and 1927 at Presbyterian Hospital, the hospital mortality was 46 per cent. There were 3 amputations done in the lower third of the leg as compared to 20 through the leg of 20 amputations in 1930, 1931, and 1932.

The hospital mortality was reduced in 1930 to 27.2 per cent, in 1931 to 25 per cent and in 1932 it rose to 50 per cent. An average of three years—1930, 1931, 1932—revealed a hospital mortality of 37.9 per cent.

It is thus with statistics. Principles of treatment are rarely found therein. They are discovered by actual case observations. Each surgical diabetic is a clinical entity unto itself, and before therapy is instituted a sur-

mation of the extent of their local and systemic pathology and the amount of surgical operative interference each will stand is imperative for their proper treatment.

TABLE III

	Number of surgical diabetics	Total hospital charges	Total paid by patients	Deficit to hospital	Average cost per patient to hospital
1930	59	\$11,266.45	\$4,904.19	\$6,362.26	\$107.83
1931	40	\$7,109.79	\$3,879.67	\$3,230.12	\$80.75
1932	73	\$17,874.82	\$6,030.98	\$11,793.84	\$93.06
Total		\$31,251.06	\$14,814.84	\$16,436.22	\$95.27

The 172 surgical diabetic admissions to Presbyterian Hospital in 1930, 1931, and 1932 cost the hospital \$95.27 each.

CONCLUSION

(1) Segregation of surgical diabetics, and the relegation of their care to one or a group of surgeons with the constant and daily supervision of a medical attendant has permitted the clinic at Presbyterian Hospital to simplify the care of these patients and obtain a reduced mortality in the group as a whole, and particularly in the amputation group.

(2) We have simplified routine laboratory investigations to the necessary minimum, and have shown patients, the House Staff and nursing personnel, that which can be accomplished in the treatment of surgical diabetics in the hospital without the use of extensive laboratory facilities.

(3) The value of prophylactic treatment of extremities, calluses, corns, the skin, abrasions, contusions, or puncture wounds in diabetics, is strongly emphasized. If a minor surgical lesion would immediately receive the intensive treatment it deserves, there would be fewer life threatening, major surgical conditions requiring prolonged hospitalization and extensive surgery. The number of extremity infections eventually coming to amputation which began with cutting a callus is still startling.

(4) Surgical diabetics are increasing because, with the decrease of corns, and the increased average longevity given this group by insulin, more diabetics reach the decades of life in which the natural pathology of their age, plus their diabetes, exposes them to complications requiring surgery. Unfortunately, there has been no noticeable decrease in arteriosclerosis in diabetics.

(5) A distinct surgical diabetic follow up clinic is necessary for a proper evaluation of previous and future instructions.

SURGERY IN THE PATIENT PRESENTING THYROID DISEASE

By RODERICK V. GRACE, M.D., and CARNES WEEKS, M.D.

New York City

Read at the Annual Meeting of the Medical Society of the State of New York, April 5, 1933, New York, N. Y.

When hyperthyroidism is present at the same time as any other surgical condition, we believe that hyperthyroidism is the more urgent and important condition and should always have surgical relief first. Until the thyroid patient has had this condition corrected by operation, no other surgical procedure can be carried out on him with any degree of safety. Although in recent years that destructive group of symptoms known as the thyroid storm or crisis has been seen less frequently, it occurs often in its overwhelming form when surgery is carried out on any patient before the accompanying hyperthyroidism has been corrected. The postoperative symptom complex which occurs in these patients may not be recognized early enough for effective treatment if the patient's history or physical examination have not previously indicated that hyperthyroidism has been present. Even when the condition is recognized, the usual therapy may be ineffective and the patient overwhelmed by the symptoms of thyrotoxicosis. While one learns from scattered sources, details of the unfortunate results in cases in which other surgical procedures have been attempted on patients with hyperthyroidism, the literature on this subject is extremely sparse.

Andrews, Greene¹, Goodrich², and C. Mayo, 2nd, have variously discussed it. We believe that it warrants further emphasis and wish to add personal observations based on 16 cases. This group consists of 7 cases of our own and 9 cases of other surgeons who have thoughtfully placed their data at our disposal.

In three of these 16 thyroid patients, minor surgical procedures had been carried out. These surgical treatments were, respectively: the extraction of a tooth; incision of a paronychia; and the excision of a sebaceous cyst under local anesthesia. In each instance there was a marked aggravation of the coexisting thyroidism. These reactions were from a mild to a very severe degree. Fortunately, in none of these cases did a fatality result.

That death may occur under such minor surgical procedure has been indicated by

Greene who recently reported on "fatal thyrotoxicosis occurring after an injection for varicose veins." One undertakes, therefore, even a minor surgical procedure in the presence of thyroidism with considerable risk. There are emergency circumstances under which minor surgery has to be carried out. Under these conditions the surgeon may expect a thyroid reaction of varying degree and should be prepared to institute early and effective therapy to combat it. The therapy of these cases will be discussed later in this paper.

The remaining 13 patients were subjected to what might be classed as major surgical operations. In 4 of these, the operation could not be deferred being of an emergency nature. The acute surgical conditions demanding operation in these patients were as follows: acute appendicitis; perinephritic abscess; acute intestinal obstruction due to a peritoneal band; and rupture of the spleen. The other major surgical conditions for which these patients were treated were of a chronic nature. This chronic group of cases showed respectively: inguinal hernia; gallbladder disease; fibromyomata of the uterus; carcinoma of the breast; and rectal polyps. In this series of 13 major operative cases there were 5 deaths following operation. Death in all of them was evidently due to an aggravation of the previously existing hyperthyroid symptoms. These symptoms increased rapidly after operation. In 3 of these cases, death occurred in eighteen to sixty hours postoperatively, in a characteristic thyroid storm. The condition was of such an acute nature that the patients were overwhelmed by the rapid increase in their symptoms of hyperthyroidism that had previously been present in a more quiescent degree. The clinical picture was marked by an acute progressive rise in temperature and pulse, out of proportion to what the surgeon may have expected in view of the operative procedures which had been carried out. In these fatal cases, the symptoms were uncontrollable from their onset. Restlessness and great emotional instability, were also very prominent symptoms to be succeeded by exhaustion, coma, and death. Iodine was the apparent need of these patients, but failure to recognize the postoperative reaction as

thyroid crisis caused its omission. Iodine given intravenously might have succeeded in lessening or abating this condition. It is the method of therapy in which favorable results have been reported by others in postoperative thyroid crisis. We wish to cite the experience of Goodrich² and Cunniffe³ in meeting this condition. Goodrich mentions 2 cases in which the thyroid storm was controlled by the use of sodium iodide intravenously at a time when all methods of iodine administration had failed to give relief and when the patients' symptoms of hyperthyroidism had progressed until fatalities seemed probable. The prompt and dramatic effect of this method of giving iodine under these circumstances recommends it as the method to be followed. The following is a quotation from the Goodrich report:

The first twenty-four hours after operation were uneventful. Thereafter ensued the typical postoperative complications with rising pulse, rising temperature, persistent and increasing nervousness and anxiety, dyspnea, and after thirty-six hours an evident failure in circulation. Lugol's solution was increased in dosage. Fluids were given by hypodermoclyses. Glucose was introduced intravenously in doses of 250 cc. of a 10 per cent solution. Restlessness was treated by morphine. Seventy-two hours after operation the patient seemed moribund with livid countenance, pulse 180, respiration 36, tremor constant and restlessness and anxiety with prostration for supremacy. Drs. Frank B. Cross and Irving Cabot saw her in consultation. In view of the unanimous opinion of physicians and surgeons that the indicated remedy was iodine and because the Lugol's solution failed to meet this indication, sodium iodide solution, gr. 15, was given intravenously at first followed by a similar dose after three hours. In four hours, the enthusiastic house surgeon telephoned to me: "A miracle has happened! This woman looks almost well." Our next observation confirmed this impression. The patient was calm, comfortable, with better color and slower pulse. Two doses were given the two days following with recovery resulting."

Cunniffe reports the use of sodium iodide intravenously in a thyroid patient who needed an emergency operation for rupture of the spleen. He found that by giving the iodine by this method, he was able to diminish the expected postoperative hyperthyroid reaction, and prevent the occurrence of a crisis. In view of these reports and in the light of the possible ineffectiveness of iodine given by the usual methods, we consider that the severity of the postoperative reaction in these cases can be lessened and the crisis successfully met by the intravenous use of sodium iodide. This medication may be repeated at intervals until the pulse rate, temperature, restlessness and mental activity by their abatement indicate that the acute thyroidism is under control. When the thyroid crisis is passed or con-

trolled, the frequency of the intravenous medication may be diminished, or iodine may be given by some other method. While we have stressed the method of using iodine under these conditions, the other usual postoperative measures, such as forced fluids, glucose, sedatives, are also of great use in combating the thyrotoxicosis. I would like to report a resume of the case histories of several of the fatal cases.

(1) The patient a woman of 44 was seen in consultation three weeks ago following an operation for the removal of a chronic gallbladder infection. The history obtained was that six days following the operation for cholecystectomy the patient developed an acute thyrotoxicosis. The family, when questioned later, said they had noticed a lump in the patient's neck accompanied by marked nervousness over a period of two years. The patient when seen was in extremis with a pulse of 110, vomiting, diarrhea, temperature of 102° to 103° F., marked dehydration and extremely apathetic. There was a small adenoma situated in the right lobe of the thyroid gland and a loud bruit was heard over both superior thyroid arteries. In spite of the institution of continuous intravenous glucose and saline accompanied by iodine in the form of Lugol's solution the patient died one week after our first visit and twenty-nine days following the original operation. Five days before the patient died a large dose of x-ray was given over the thyroid region in hopes that it might accomplish some benefit but it was without result.

This case illustrates the danger of doing major abdominal operations in the presence of toxic adenoma of the thyroid. In this case unfortunately, adequate measures to combat the thyrotoxicosis were not taken until too late.

(2) Patient Miss M. Q. age 41 was first seen in the early part of March 1926, her previous history had been entirely negative except that she had had symptoms of hyperthyroidism about two years ago. She was treated at that time by a specialist and was very much improved. She returned to work had no further trouble, and had no recurrence of her symptoms. During the last few months she has experienced a desire for frequent urination, she had a very severe pain deep in the pelvis and said she felt as though something was being forced down between her legs when she walked for any distance. She also noticed a swelling in the lower part of her abdomen and a movable hard mass could be felt by palpation just above the pubes. A rectal examination showed a mass in the pelvis extending to the right side, but which was connected with the uterus. The diagnosis was fibroids of the uterus. Physical examination of the patient was negative pulse and heart normal, and she was perfectly normal throughout except that a small hard adenoma in the left lobe of the thyroid could be felt. The basal metabolism test was plus seven. She was kept in bed for two weeks and the operation was then postponed for three more weeks, therefore she really had about five weeks' rest. She was then prepared for the operation in the ordinary way disregarding, of course, her previous thyroid history on account of her basal metabolism test and the negative findings in the physi-

cal examination. She was not given Lugol's solution or any other form of iodine preoperatively.

The operative procedure was done under gas-oxygen-ether anesthesia. The abdomen was opened in the median line below the umbilicus and a large tumor was found between the layers of the right broad ligament extending deep into the pelvis. Incision was made in the broad ligament and a large lobulated fibroid enucleated from the pelvis. It was attached to the right side of the uterus. There was very slight oozing from the tumor bed. The operation was easy of execution, and in order to get out of the abdomen quickly, the cavity from the tumor was lightly packed with gauze and the broad ligament was sewn high up to the peritoneum, shutting off the abdominal cavity of the tumor bed which contained the gauze. When we enucleated the tumor, which took a very short time, the anesthetist informed us that the patient was reacting very badly. The pulse rate was very rapid and he asked us to end the operation as soon as possible. A saline infusion was given at the time of the operation. There was no bleeding and no cause was found for this very great change in the patient. The patient was treated for shock with an infusion and morphine, the infusion being given in the operating room. Her temperature was 102 °F. about an hour after the operation and then gradually rose for three days until on the third day it reached almost 109 °F. Her pulse was fast and irregular, rising finally to 180. She developed classical symptoms of a thyrotoxicosis, became very restless, noisy, talkative, and irrational, fumbling and thrashing about the bed. She was treated by the ordinary methods of ice-bag to the head, cold sponges, infusions and a transfusion with the usual cardiac stimulation of digalen, caffeine sodium benzoate, and with morphine; nevertheless, the temperature continued to rise and on the third postoperative day the patient died of thyrotoxicosis. No iodine was in the treatment of this patient. Postmortem wound inspection revealed no signs of hemorrhage in the operation area.

In reviewing this case, iodine especially by the intravenous method might have been of the greatest value. This case also illustrates the dangers of operating on a relatively mild and previously treated case of hyperthyroidism.

(3) Patient, A. J., age 40, previous history: Ten years ago she was told by a physician that she had an abdominal tumor. She had three pregnancies; two children, 17 and 8, respectively. The third pregnancy resulted in an abortion three years ago. There was no history of tenderness or of bleeding. She had some symptoms due to perineal laceration. Patient was sent in as a case of fibroid of the uterus. For three months she has had some dyspnea, ophthalmia, and palpitation. There has been some general increase in the thyroid gland for the past sixteen years. On physical examination the patient appeared nervous. The thyroid was symmetrically enlarged and pulsating. There was an abdominal tumor the size of a grape fruit. X-ray examination of the chest showed the heart not to be enlarged. Electrocardiogram and kidney function tests were negative; basal metabolism 16 plus. A medical consultation was obtained, and the heart was reported adequate for operation. An operation was performed on March 20, 1926. A moderately difficult hysterectomy. The patient died on the second day after operation. The temperature ascended to 105° F. and to pulse rate to 150 and upward. The patient

had a rapid pulse during the operation. An autopsy showed colloid areas and adenomas of the thyroid. The abdomen showed no evidence of any complications resulting from the operation, such as hemorrhage or infection.

The significance of the patient's thyroid symptoms was not impressed upon the operator until it was too late to administer iodine therapy. The severity of the crisis and its rapid fulmination overwhelmed the patient very early.

The history of the fatal cases in this group show several very interesting points. In the first place, the patients' histories pointed to the fact that hyperthyroidism had been present for some time previous to the operation but that the condition was considered cured or controlled by conservative methods. These conservative methods were primarily those obtained by prolonged rest in bed and the use of iodine or x-ray therapy. They had been used either alone or in combination by the medical advisers of these patients. As a result, the patients felt themselves to be cured of their hyperthyroidism, and this opinion was also shared by their surgeons in view of the fact that the present symptoms of hyperthyroidism were of a relatively mild character. Previous treatment of these hyperthyroid patients may, therefore, have lulled their surgeons into a sense of security. The hazard of the thyroid crisis is potentially present in these patients, and surgical trauma may make it actual. Anesthesia, the operative and psychological shock, all play unfavorable parts in this connection. Wound exposure, prolonged handling of tissue, and hemorrhage also are factors of an unfavorable nature. Any of them may aggravate the preëxisting thyroidism in a serious way. All of them may offer a postoperative burden that too often ends in fatality.

One of the first observations that hyperthyroidism is manifesting itself unfavorably may be noted in these patients just previous to operation. At this time the patient may indicate by mental and motor activity as well as by a marked increase in pulse rate, the earliest manifestations of the crisis that is going to follow. Should a history of previous hyperthyroidism have been elicited, the patient could be protected by the use of iodine therapy. Later on it has been characteristically noted by the anesthetists that the quality and rapidity of the pulse rate in these patients has been out of proportion to the surgical procedure which was being carried out. The pulse rates in some of these simple surgical procedures have risen to as high as 150 to 180 a minute, seemingly without reason. At this time, too, the patient might be protected by

the use of iodine therapy intravenously. Therefore, in a patient who is a suspected hyperthyroid, either by history of physical examination, by the prevention of a crisis, or by the diminution of its severity, may be met before or during operation, and the use of the iodine at such a time would offer the patient an opportunity to escape the hazard of the acute thyroidism that is impending.

One of the fatal cases in our series had been treated previously over a long period with small doses of iodine. Following a severe operation he showed in a few hours the serious symptoms of hyperthyroidism culminating in a thyroid storm with death eighteen hours later. It is well known that thyroid patients who have been taking iodine over a long period develop a tolerance to it. Having become iodine-fixed, they fail to derive the benefit from its use at a time when they need it most. Such a patient offers a peculiar problem. The situation can arise in which acute appendicitis or a ruptured viscus, may occur in a previously iodized thyroid patient. The dilemma offered the surgeon is serious and the outcome apt to be unfortunate; however, it is met. At this time, therefore, we wish to emphasize that iodine when used in a form

other than as a preparation for operation increases often the unfavorable symptoms of hyperthyroidism and adds to the mortality.

CONCLUSIONS

In a group of 16 cases on whom other surgical operations were performed in the presence of coexisting hyperthyroidism, there were 5 deaths. This mortality of 30 per cent or more is high for any type of surgery. It can be diminished greatly by following out that surgical precept that is too often forgotten when any surgical condition coexists with hyperthyroidism. The thyroid condition demands primary surgical attention. This precept is to be violated only in the presence of such surgical conditions as demand emergency operation. Under such circumstances the surgeon should expect a marked aggravation of the preëxisting symptoms increasing possibly to a thyroid crisis, and must make early effort to combat these symptoms. Iodine intravenously, offers him an effective and sure method of therapy in certain of these cases.

SURGERY IN PATIENTS PRESENTING PULMONARY DISEASE

By FRANK B. BERRY, M.D.

First Surgical Division, Bellevue Hospital, New York City

Read at the annual meeting of the Medical Society of the State of New York, April 5, 1933, New York, N. Y.

In approaching the subject of how to manage best the surgical patient with accompanying pulmonary complications, two divisions appear at once. First, are we concerned with an acute respiratory infection? And, second, that group in which a further distinction must be made between those patients who undergo surgery in the presence of an already existent pulmonary condition, and those without previous trouble in whom, during their postsurgical convalescence, a respiratory infection appears. These two questions of such vital importance to the patient are always a source of concern and worry to every conscientious surgeon, and on the appreciation of them will depend his successful fulfillment of his obligation both to the patient and his profession.

I purposely omit mention of the surgery of pulmonary tuberculosis *per se* or of chronic

pulmonary suppuration, as I believe both of these fields are too narrow and specialized for the scope of this paper.

We know that the incidence of respiratory infection in our latitudes is highest from November to May. Some of us fail to bear in mind, however, that during this same period, particularly February to April, there is also a great increase in latent or potential respiratory infection. By that I mean that many persons in good health are transient carriers of pathogenic organisms in their upper respiratory tracts. Of these a hemolytic streptococcus is the most common, but in addition there are also potentially virulent pneumococci, staphylococci, influenza bacilli, and also the pathogenic anaërobes. Approaching the subject from another angle, that of wound infection, Meleney has clearly demonstrated this with reference to the hemolytic streptococcus. The same result can be shown by nose and throat cultures of ward patients, as

Rosenow and I found in the hospital at Fort Reilly in April, 1918. These observations are pertinent to all surgery during our winter months and cognizance of them will lessen our respiratory and septic complications in those whom we consider normal patients.

PREPARATION

PREOPERATIVE.—In the presence of an acute respiratory infection every one is agreed that all surgery should be avoided unless absolutely necessary. On the other hand, an emergency should be met fearlessly. In the case of an upper respiratory infection every effort should be made preoperatively to lessen the secretions and minimize the chance of spread during the operative procedure. This can be accomplished by the use of ephedrine in the nose, belladonna or atropine orally or hypodermically, and liberal swabbing of the throat with 2 or 4 per cent mercurochrome directly preceding operation. With the very ill patient, one with pneumonia for example, every effort must be spared the patient. The fluid supply of the body should be maintained. If fluids are contra-indicated by mouth they may be given by rectum or, if necessary, by a preoperative clYSIS or infusion. In the presence of pneumonia or with injury to the chest or lungs, owing to the temporary imbalance of the cardiorespiratory system, infusions should be administered in repeated small amounts or else by the continuous drop method, and transfusions of over 400 c.c. should be given with great care except for hemorrhage; rather they should be repeated and be relatively small in amount.

All these patients should be kept well covered with light, warm absorbable clothes and should be kept out of draughts. They should not be smothered, neither should they be shorn. No rule of thumb can be applied. Different people are accustomed to different types and weights of clothes and so far as possible their usual habits should be continued.

The patient with chronic pulmonary disease presents a somewhat different problem. First, urgent surgery should not be delayed. The most common alibi for procrastination is the diagnosis of tuberculosis typhilitis with abscess or obstruction in the one who already has pulmonary tuberculosis. In my own brief experience I have several times seen the true condition of acute appendicitis unrecognized on this account and the chances for successful results of early operation thus thrown to the winds.

Interval surgery with underlying chronic pulmonary disease offers still another phase

of the whole question. Meddlesome and unnecessary operations are, of course, unwarranted. But any procedure which would benefit the patient unhandicapped by pulmonary disease will probably benefit one so afflicted even more. In preparing such patients for operation the chief aims should be: first, to render the lung condition as quiescent as possible, which can be best judged by the x-ray; second, to build up the general condition of the patient so that he is eating and sleeping well, gaining in weight, and has a good mental attitude; third, by following out the above, to reduce all symptoms of toxicity to a minimum; and, fourth, to minimize the chances of the spread of his pulmonary disease during and following operation by preoperative drainage of the lungs by posture or bronchoscope. This may require only a few days or several months, but the results will more than justify the delay. Furthermore it may first be necessary to institute some minor operative procedures on the lungs themselves such as artificial pneumothorax, repeated bronchoscopies, phrenicectomy, or division of adhesions in cases of tuberculosis under pneumothorax therapy.

PROCEDURE

OPERATIVE.—Preliminary to the operation itself, the choice of anesthesia is to be considered. This procedure has made such rapid strides within the past decade as to leave us rather bewildered. Our ideas as to basal anesthetics have been extended so that we are now using these drugs less routinely and more according to selection of cases. In the presence of an acute respiratory infection avertin, nembutal, or sodium amytal may be administered with safety in moderate dosage, or a combination of either of the last two in still smaller dosage, or luminal, may be used in conjunction with morphine and hyoscine. When such drugs have been given, enough time must be allowed to elapse before proceeding further, following which the operative procedure can be carried out under local or light general anesthesia. If the latter is to be employed, either is, of course, contra-indicated. As between ethylene and nitrous oxide, the former is to my mind far superior. It affords better relaxation and an abundance of oxygen, which nitrous oxide does not, and because of this less strain is placed on the right side of the heart with the ensuing pulmonary congestion, as so frequently happens with the asphyxia of nitrous oxide.

The best choice of the anesthetic, however, for this group of cases is spinal, regional, or

local anesthesia. Interference with normal respiration and danger of aspiration is reduced to an absolute minimum. With spinal and block anesthesia such perfect relaxation is obtained that technical procedures are facilitated, gentleness of manipulation is encouraged, and the operating time reduced. All of these are of great importance. More or less amnesia and analgesia are first procured by veronal, or morphine, with or without hyoscine, and any undue fall in blood pressure can be prevented by hypodermic injection of ephedrine, five minutes before the solution is introduced into the spinal canal and repeated later if necessary.

May I make a short digression here on the most common surgical condition with which we are confronted in acute pulmonary disease, empyema? Until thick, frank pus gives evidence of safe protecting pleural adhesions no open operation should be performed. The principles so ably stated by Graham during the World War still hold and failure to observe them will result in aggravation of the condition and an increase in the mortality. Rather drainage must be maintained, and the lung allowed to reexpand, either by repeated aspirations, or by the institution of closed catheter drainage with the catheter introduced at the lowermost level of the cavity. Depending upon the presence of a bronchial fistula, dyes or antiseptic solutions may, or may not, be used. When this method of treatment has failed and the pus has become thick, then, and then only, should open drainage be established. This is best accomplished by the removal of a short piece of rib under local anesthesia or ethylene, preferably the former. Here again the essence of success lies in proper placing of the opening at the bottom of the cavity. The cavity should be thoroughly cleaned of pus and fibrin, and may then be temporarily packed with gauze or simple tube drainage established with frequent Carrel-Dakin irrigation.

This choice of anesthesia applies also to internal surgery in cases of chronic pulmonary disease. Whenever possible, spinal, block, or local anesthesia are the anesthetics of choice for the reasons already stated. Lately we have been employing high spinal anesthesia for some of our upper stage thoracoplasties with good results. My feeling here, however, is that there is an unjustifiably thin line of reserve and safety. Respirations tend to be shallow and the ability for effective cough impaired; therefore it is my opinion at present that spinal anesthesia should not be advised for operations above the level of the midtho-

racic region. In this group rectal ether, inhalation anesthesia, ethylene, or nitrous oxide preceded by adequate basal preparation can be used with perfect safety. Included in some of the newer apparatus is a soda-lime-carbon-dioxide absorber. This is a great improvement over the older methods, and when used a perfectly quiet natural sleep is produced free from hyperpnea, dyspnea, or respiratory irritation, and unaccompanied by the sweating, exhaustion, and cardiac strain which so often accompany ordinary inhalation anesthesia. This is, moreover, of particular importance in cases of chronic pulmonary disease and it is quite conceivable that it may become the method of choice for all these patients.

Let me say a few words about the basal anesthetic in chronic pulmonary disease. Avertin and amytal are contra-indicated as they are respiratory depressants with a prolonged action. Nembutal in small doses is better assimilated. A preoperative preparation which I have found quite satisfactory consists of sodium bromide, gr. 90, the night before operation. Luminal, gr. 3, or nembutal, gr. 1½, repeated once is given one and a half hours before operation, and morphine, gr. 1/6, and hyoscine, gr. 1/200, an hour later. This usually insures a restful immediate preoperative period and a quiet anesthesia, yet one in which the cough reflex has not been already abolished and from which the patient promptly awakens and resumes his normal respiratory level. More morphine can always be given if necessary at the start of, or during, the anesthesia.

As to supportive measures during the operation itself, if it is of sufficient magnitude, 1,000 c.c. of saline given slowly by rectum early may obviate the need of an infusion or hypodermoclysis later. Or, if this has not been done, a coffee enema immediately following operation may accomplish the same result.

Following operation, the type of dressing is first considered. Tight strapping of the abdomen and lower chest should be avoided; this splints the diaphragm and lower ribs and favors the development of atelectasis, stasis, and pneumonia. The same applies to dressings on wounds of the chest itself. Once the dressing has been properly applied, the patient should be placed in warm, clean clothes, kept out of draughts, and returned to a warmed bed as expeditiously as possible. If the operation has been on, or within, the thorax, the patient should always be placed on the affected side to help drainage, to pre-

vent intrabronchial drainage from the bad to the good lung, and to insure maximum comfort and freedom of respiration. Cough should be facilitated; it rids the bronchi of their accumulated secretions and aerates the lungs. In order to do this, it is frequently advisable to place the foot of the bed on shock blocks until the patient has regained full control of himself. After this his position should be changed at regular intervals.

Again let me urge you to consider the individual habits of the patient as to clothes and fresh air. Allow plenty of fresh air so long as it does not blow directly on the patient; the temperature can be easily regulated. If the patient is accustomed to heavy flannels, now is not the time to make a change. Conversely do not give an inadvertant hot pack and sweat with blankets because of nursing routine irrespective of the time of year and personal living conditions of the patient. He should be kept warm and dry, not in a profuse perspiration. Adequate fluids should be supplied for two reasons: first, to supply the bodily needs of the patient, and second, to prevent increased viscosity of the bronchial secretions.

As to drugs and sedatives, I deplore their too liberal or routine use postoperatively. Morphine is the chief culprit and it is usually prescribed in unnecessarily large amounts. It is a distinct respiratory depressant, promotes a shallow and slow respiration and inhibits cough. Given only when needed and in 1/16- to 1/8-grain doses it will in the great majority of cases accomplish all the 1/4-grain dosage accomplishes without the deleterious effects of the latter. With these smaller doses the patient is kept comfortable without being allowed to swing through a recurring arc with pain on one end and stupor on the other. Frequently this very small dose may be repeated at three-hour intervals with good effect. Furthermore, chloral hydrate and sodium bromide by rectum, or codeine or sodium luminal subcutaneously may be sufficient by themselves. Much attention has been given lately to the use of carbon dioxide at the close of the anesthesia and during the succeeding six hours. If used with care, this is helpful; otherwise it acts as a respiratory irritant and is also annoying to the patient. The mixture to be inhaled should never be stronger than 5 per cent carbon dioxide, preferably 3 to 4 per cent. Two or three minutes of this once or twice an hour will give the desired hyperpnea and pulmonary ventilation; too long periods of hyperpnea are exhausting.

Even with the best of care a certain num-

ber of respiratory complications will develop postoperatively no matter what type of anesthesia is used. The simplest is the group of upper respiratory infections. Should any of these occur in spite of all the precautions taken, they are met with the usual methods at one's disposal. The more serious have to do with the lungs themselves. The most common of these is a partial or complete atelectasis, the so-called massive collapse.

In the great majority of instances, if not in every case, the precipitating cause is bronchial obstruction due to accumulated plugs of tenacious or inspissated mucus, and the predisposing conditions which in turn favor this development are often the fault of the surgeon. These are tight strapping of the abdomen and lower chest, abolition of the cough reflex as from the use of opium to the point of stupor, dehydration with resultant thickening of bronchial secretions, shallow respirations, retained secretions, and abdominal distention. I have discussed all but the last-named. This may be handled in two ways: by attempts at prevention or treatment after it occurs. Every effort should be made to prevent and control it. For the past year in all abdominal cases I have used pitressin intramuscularly, one ampule every four hours for twelve doses, with exceedingly good results. Rarely it may not be tolerated, but as a general rule if begun during the operation or immediately thereafter, gas pains and distention seem to be distinctly less than when it has not been used.

Atelectasis occurs usually within the first forty-eight hours and may be at once suspected by its sudden onset with dyspnea, a possible chill, and prompt jump in temperature and pulse rate. The diagnosis may be confirmed by the physical signs of dulness, absent breath sounds, a few rales, elevation of the diaphragm, pulling of the mediastinum to the affected side, and decreased mobility of that side of the chest. X-ray is confirmatory and diagnostic. Treatment consists of turning the patient on the unaffected side and slapping the affected side briskly, inhalations of 5 to 10 per cent carbon dioxide and oxygen, the administration of a strong expectorant or an emetic, and, if these lesser measures fail, the bronchoscope. This condition should be immediately recognized and relieved, otherwise the infected mucous plug prepares the ground and pneumonia follows.

Pneumonia, bronchitis, or lung abscess may be caused by aspiration at the time of operation and when they occur require immediately the best of medical advice and therapy and

possibly subsequent surgery. This brings us finally to the embolic group, some of the most fearsome of all surgical complications. They usually make their appearance relatively late—from five days to seven or eight weeks. The simplest is the bland pulmonary infarct accompanied by sharp pain in the side, bloody sputum, and a friction rub. Should this occur, the patient's blood should be immediately analyzed as to its thrombin-fibrinogen balance and low fat and protein diet and sodium thio-sulphate given if this is found high. The work of Bancroft and Stanley-Brown would indicate these to be very real factors in the development and treatment of thrombi and emboli.

The embolus may be bland and small. If infected, there will be a surrounding pneu-monic zone and eventual abscess formation; or, it may be the precursor of a series of emboli or the single fatal type. At all events the question at once arises whether the surgeon should not be prepared for an immedi-

ate Trendelenburg operation. My personal feeling is that he should, and everything should be in readiness. This will be facilitated and the chances for success enhanced if the situation is explained and the simple preliminary operation of removal of the second and third left costal cartilages at once undertaken under local anesthesia.

SUMMARY AND CONCLUSIONS

In the foregoing I have attempted to outline a working basis which the general surgeon can employ in his contact with patients suffering from pulmonary disease. Like the diabetics and thyroid cases, they present problems of their own and some points of difference from the uncomplicated surgical patient. For their successful management careful thought and planning are required, swiftness and gentleness are at a premium, and accurate diagnosis and the courage founded on sound surgical judgment are essential.

768 PARK AVE.

SURGERY OF INFANCY AND CHILDHOOD

By EDWARD J. DONOVAN, M. D.
New York City

Read at the annual meeting of the Medical Society of the State of New York, New York, N. Y., April 5, 1933.

Surgery of infancy and childhood includes so many elements in addition to the treatment of the actual surgical condition that the management of this branch of surgery necessarily differs from that of adult surgery. For example, an infant with an appendix abscess not only requires many dressings, but also careful attention to feeding.

The surgeon who hopes to be successful with infants and children must understand child psychology. He must be patient and sympathetic and have a personality congenial to that of a child. He must use the utmost care and gentleness in all manipulations of painful structures. A friendly spirit established at the initial examination may go a great way toward the successful accomplishment of the necessary surgical procedure and its attendant difficulties.

Infancy may be considered as that part of early life from birth to the completion of the first dentition, or about two and one-half years. Childhood extends from this period to the development of puberty. There are

but few surgical conditions which are peculiar to infancy and childhood, the majority of diseases being the same as in adults, except that they are modified by the conditions which characterize early age. These modifying factors are often not detrimental in their influence. While the absence of speech in an infant deprives the examiner of the subjective help he obtains from an adult, it is an advantage in that it makes the surgeon depend more upon his powers of observation and his exercise of good judgment.

Another factor affecting the course of any disease in a child is the process of growth and development. It is this that often makes disease sudden in its onset, short in its course, and, perhaps, intense in its manifestations. It is this factor, also, which comes to the aid of the surgeon in overcoming by growth the mal-alignment of a fracture or the spontaneous healing of an incisional hernia.

The resistance of children differs from that of adults. As their tissues are not affected by degenerative diseases, they have the highest powers of recuperation.

One must be ever mindful of the fact that there is a definite limit to the amount of sur-

gery that an infant or child can stand. Barrington Ward states this fact plainly when he says: "The standard of operative treatment of infants and children must be high technically as they resist powerfully to a certain point, but the fall is precipitate."

There is no operative skill that can overcome the results of delays in diagnosis. A child with a ruptured appendix and general peritonitis in the hands of a master surgeon probably does not have as good a chance of recovery as a child who has had his appendix removed before rupture, by someone far less skillful. Early diagnosis is often difficult, but it can usually be made if the examiner follows a fairly definite plan of examination. He must seize his opportunities as they present themselves, be ever ready to change his plan of attack, and be gentle but thorough at all times.

Fortunately, some of the old-established methods of preparation for operation have fallen into discard. The custom of starvation and purgation has no place in modern surgical procedure. The ability of an infant to stand starvation has previously been underestimated, and, now, we fully appreciate the importance of body fluids both before and after operation. Purgation and starvation not only upset this fluid balance by waste of valuable body fluids, but purgation, by irritating the intestinal tract, definitely increases post-operative discomfort. Now we aim to build up a reserve of body fluids before operation and to maintain this balance during the most critical part of the child's convalescence. There are many ways in which this may be done. Fluids used are 5 to 10 per cent glucose and saline given by infusion, hypodermoclysis, proctoclysis or intravenous drip. We have found this latter method, as worked out by one of the attending pediatricists at the Babies Hospital, very useful, and we have been able to give a continuous drip infusion for as long as five days. It is a most satisfactory method, is applicable to many cases, and it is given so slowly that it is free from the danger of overloading the right heart.

Transfusion must not be forgotten in the preoperative preparation of infants and children. This most useful adjunct is probably one of the greatest aids. It is not difficult to do, has a wide application, and has few contra-indications. The smallest infant may receive 20 c.c. of whole blood per kilogram of body weight by any of the approved methods. We prefer the Lindeman method. I believe, however, one must be most careful in using

a transfusion or infusion in any case with a complicating pulmonary disease because of the danger of overloading the right heart.

One must ever be on his guard against acidosis. This condition is precipitated by starvation and purgation. It may be most troublesome, and it is to avoid this complication that we allow the child to have his usual diet on the day preceding operation and allow water to be taken to within one hour of the time of operation. For the same reason, fluids are forced after operation and probably allowed earlier than to most adults. Saline and glucose solutions can be used to keep a child free from ketosis for as long as a week. The best example of the effect of fluids is shown in the group of children with pyloric stenosis. They probably have the greatest fluid unbalance of any group of children that we see. This is particularly true if they have been vomiting for some time. So striking is the change in these patients after three or four days of forced fluids, that one would hardly recognize them as the same babies. The continued vomiting causes a decrease in chlorides so that saline to replace lost fluid is better than glucose in this instance. In this way, the poorest surgical risk may be converted into a safe one in a short time. The mortality of this group at present is decidedly below 1 per cent, and I am sure that this is due entirely to proper restoration of fluid balance before attempting operation. We have not found it necessary to do preoperative blood chemistry as diabetes and nephritis may be diagnosed in other ways, and taking blood may be difficult.

Status lymphaticus is a condition that may cause the surgeon great anxiety, and almost every surgeon has had a patient die very suddenly perhaps while being anesthetized. The postmortem examination often reveals a large thymus and hypertrophy of the lymphatic elements. In other cases, no cause for death is found. There is a great difference of opinion regarding this condition, and it is questionable how large a part the enlarged thymus plays in the picture. It is practically impossible to routinely x-ray the chest of each child for enlarged thymus. If the condition is suspected, an x-ray may be of great help in confirming the suspicion, and, if an enlarged thymus is found, it is better to postpone any elective surgery until the thymus is treated with radium or x-ray.

It is not unusual to find that a child has an unexplained temperature at about the time

planned to operate upon him. This may be due to dehydration, an acute ear, a red throat, or the earliest sign of one of the exanthemata. The temperature is often of no consequence, but it is a safe rule to postpone for a few hours at least, any elective operation on an infant or child who has an unexplained temperature.

The question of anesthesia is one that troubles most parents, but it is one that need concern the surgeon very little if he insists upon the anesthetist's using open cone ether and makes sure that he devotes his attention exclusively to the patient during the operation. Infants and children tolerate open ether very much better than adults, and are not nearly as sick after it as older patients are. It has been our practice to use ethyl chloride for induction followed by open drop ether. The indications for local anesthesia, whether it is infiltration, field block or spinal, are very limited, and necessary only where there is an acute respiratory infection present when surgery needs to be done. Avertin as a basal anesthetic has many uses in children, and it seems to be tolerated better by them than by adults.

Regarding actual surgical procedure, the most rigid asepsis must be practiced at all times. Children are very susceptible to infection, and every means at hand should be used to guard them against it. The operation should be carefully planned and executed with as much dispatch as is consistent with gentleness, careful handling of tissues, and strict hemostasis. The temperature of the operating room should be about 72° F.; the child should be protected from unnecessary exposure, and body heat maintained during operation. Everything should be ready to start the operation before the induction of the anesthesia so as not to keep the child under anesthesia longer than is necessary. At the conclusion of the operation, the child should have any moist coverings changed for dry ones before leaving the operating room. He should be placed in bed with his head lowered until he has fully recovered from the anesthetic. A tank of oxygen and tongue forceps should always be at hand in the recovery room. No child should be left alone until completely recovered from the anesthetic.

Plain fluids are allowed as soon as nausea and vomiting have ceased, and children may be given tap water or glucose by rectum immediately after operation. If there is any tendency to acidosis, infusion or clyses may be started before the child awakes. As a rule, it is no trouble to force fluids in children

after operation. Solid food may be given on the second or third day after operation. All incisions should be dressed every two days because of the danger of contamination from soiled diapers.

Most of the usual postoperative complications of adult surgery are entirely lacking in children. Pulmonary embolism is practically unheard of. Postoperative pneumonia is much less frequent. Postoperative retention of urine is never troublesome, and cathartics are hardly ever necessary. We need to be concerned a little more about postoperative rupture of incisions in children than we do in adults, particularly in those children who are poorly nourished or who develop measles or whooping cough soon after operation. To guard against this complication, we make it a practice to use retention sutures for the deep layers, particularly for rectus incisions, and to take particular care to get an accurate layer closure of all incisions. Most children will unconsciously keep an injured part at rest, and, when once taught to lie quietly in bed, they will remain so indefinitely.

In conclusion, therefore, we may say that infants and children are excellent patients, as a rule, and splendid subjects for surgical procedures that are carefully planned and as skillfully executed as is consistent with the utmost care and gentleness in handling tissues. The surgical approach to the diseased organ should be as direct as possible as there is practically no indication in children for the so-called exploratory laparotomy of adults. Careful hemostasis is very essential, and the careless, rough, dragging upon organs and blunt dissection which in an adult result in a stormy convalescence may prove fatal for a child. There is no excuse in our day for a surgeon's performing any elective major surgery on a child without determining first that the child is in the best possible physical condition. Many a skillfully executed operation has been a failure because the child was dehydrated, anemic, exhausted, or otherwise not in condition to withstand it. There is a definite relation between the state of nutrition, the general condition, and the convalescence from any operation.

Children bear hunger, pain, cold, and loss of blood very poorly. They are very susceptible to shock and do not stand prolonged operations well. Their recuperative powers are tremendous, and, if given half a chance they will recover in the face of the greatest odds.

A CLINICAL STUDY OF PERSISTENT ENURESIS

By MEREDITH F. CAMPBELL, M. D.

From the Departments of Children's Medicine and Urology, Bellevue Hospital (New York University and Bellevue Hospital Medical College) and the Babies' Hospital (College of Physicians and Surgeons, Columbia University), New York, N. Y.

Read at the annual meeting of the Medical Society of the State of New York, New York, N. Y., April 5, 1933.

This clinical study of enuresis has been confined to children four years of age and over in whom the usual methods of treatment have failed. The data presented were obtained by systematic urological examination in 330 cases of this type and indicate that demonstrable uropathology exists in approximately two-thirds of these cases. The etiologic relationship of organic changes to the clinical syndrome of persistent enuresis is the thesis of this communication.

We should consider enuresis as a symptom and not a disease. The clinical syndrome which has been loosely designated enuresis is characterized by involuntary urinary incontinence, usually nocturnal, less often diurnal, but occasionally both diurnal and nocturnal. In the cases urologically studied and reported here the pediatricians who referred the children for examination had made the clinical diagnosis of enuresis on the above criteria (Table IV). In any discussion of enuresis the problem of nomenclature at once arises. Although the definition of enuresis has often been qualified as "involuntary urinary incontinence in the absence of urinary tract changes," in a surprisingly large number of cases, there is nothing in the symptomatology or urinalysis to distinguish the purely functional disturbances from those due to obstruction, for example. This distinction can be made only by urologic examination. It seems to me, therefore, that justifiably we should take a broader view of so-called enuresis and always bear in mind the possibility of an organic basis for the condition (Table VIII). There is a striking uropathic analogy between enuresis and "chronic pyelitis." Although the latter is erroneously assumed by the majority of physicians to be only a persistent inflammation of the kidney pelvis, urologic examination commonly reveals major urinary tract pathology such as infected hydronephrosis, renal stone, tuberculosis or even bladder diverticulum. In enuresis, congenital lower tract obstructions and inflammation are extremely common.

A child should normally acquire satisfactory bladder control by the age of thirty months and not later than the third birthday.

The theories concerning the etiology of enuresis are numerous and are concerned for the greater part with functional disturbances or irritation reference (phimosis, balanitis, oxyuris, etc.). Many of the theories are Freudian or pseudo-Freudian; it is unessential to go into them here. Antecedent disease has long been held to predispose to enuresis, yet in our series the incidence of measles, pertussis, chicken-pox, diphtheria and so forth parallels that in nonenuretic children (Tables II, III and V). However, bed-wetters as a group are apt to be slightly more "nervous." In our series, 158 were girls, 172 were boys.

The writer disagrees with those who believe that all enuresis is functional. I believe, however, that the vast majority of these cases, perhaps even 90 per cent, are functional. This large group will usually respond readily to the commonly employed medical or psychic treatment which includes the discontinuance of fluids after four o'clock, the use of the alarm clock, belladonna, thyroid extract, or strychnine, together with verbal encouragement or gold star rewards. By these methods, probably 9 out of 10 children will be cured. Yet Dr. G. L. Johnson, my associate in this work at the Vanderbilt Clinic, informs me that in 125 cases seen by him, 23 did not clear up by the usual methods and were referred to me for urologic examination. He states that "in these 23 cases are included a number that were cured simply by cystoscopy, and no further treatment was done. In addition, there were 3 cases that were helped by meatotomy and dilatation of the external urethral opening. This is a higher percentage (of enuresis on an organic basis) than you thought, but I think the explanation lies in the fact that the majority of the cases that come to me have first been treated unsuccessfully by the other men in the clinic by the usual procedures."

When intensive medical or psychologic treatment is unsuccessful after a two to four-month trial, the child is entitled to a com-

plete urologic examination. This has been the indication for examination in the cases under consideration here, examination has shown a hitherto unrecognized high incidence of organic urinary tract disease in persistent enuresis (Tables VII and VIII). Unsuspected infection is sometimes found. Yet it is this very infection which often causes the urethrorrigoitis, posterior urethritis, or prostatitis, which in turn are clinically manifested by enuresis. Moreover, microscopic hematuria due to inflammation or infection may also exist. The incidence of neuromuscular disease (cord bladder) and congenital lower tract obstructions is strikingly high. However, the foregoing conditions are only some of those commonly found in the large number of juvenile enuretics whom physicians are prone to treat by the usual means month in and month out and during which time the pathologic changes in the urinary tract are constantly and unfavorably progressing.

In the urologic examination of children with therapeutically resistant enuresis I proceed as follows: There is a careful physical examination with special attention to the central nervous system, particularly the deep reflexes and alterations in perineal sensation. In a certain number of children whose enuresis is a manifestation of neuromuscular disease, there are altered perineal sensory responses, sometimes a complete "saddle" anesthesia indicative of advanced sacral cord disturbances is found. These sensory changes have been most striking in association with anomalies of the sacrum yet they have shown no striking parallel to the common place spina bifida occulta. Still, neuromuscular disturbances of the bladder commonly exist without demonstrable cutaneous or anal sphincteric evidence.

Careful examination of the urine including culture is imperative. Females must be catheterized to avoid bacteriologic contamination of the urine. In most males, a satisfactory specimen can be obtained following retraction of the prepuce and thorough cleansing of the glands and meatus. A small amount of urine is allowed to pass before the specimen is taken for microscopic and bacteriologic investigation. Urinary infection was found in one-fourth of our patients. Urologically, we are interested chiefly in the pus, blood, and bacterial content of the urine. An unusual number of epithelial cells is suggestive of urethrorrigoitis.

The residual urine is then estimated. The patient empties the bladder to the best of his ability, he is catheterized at once and any urine thus obtained is the residuum. One of

the most striking findings in our study has been the high incidence of residual urine in these children with persistent enuresis. We found that approximately 1 in 6 (16.9 per cent) had residual urine, varying from 10 cc to over 10 ounces with an average of 25 to 45 cc. In other words, these children could not empty their bladders. I have not found this observation recorded elsewhere. Residual urine means either lower tract obstruction or neuromuscular disease. A small residuum causes a constant congestion and hyperirritability of the bladder outlet which during the day is commonly manifested by urinary frequency and at night by periodic incontinence. A large residuum frequently indicates chronic complete urinary retention and often the incontinence or enuresis is simply an overflow. The residual retention not only predisposes to infection but causes variable changes in the upper urinary tract.

A plain roentgenogram of the urinary tract is now made. We are particularly interested in the demonstration of stone or spinal defects, particularly spina bifida occulta. The latter has been said to be a common cause of enuresis but was found in only 15.2 per cent of our chronic cases, an incidence but slightly higher than the 10 per cent said to be normal for all individuals (Table VI). However, in a few instances, sacral deformities were proved etiologically related to the neuromuscular disease which was manifested by enuresis. Plain roentgenography is followed by cystography. A cystogram is made by filling the bladder with 5 per cent sodium iodide or with a 3 per cent solution of one of the new excretion urographic media (Iopax, Neo Skiodin, etc.), and then making x-ray exposures. A normal bladder outline is usually obtained but in some instances a hypotonic bladder has been found to fill the entire pelvis. In certain cases of lower tract obstruction or of neuromuscular disease there has been vesico-ureteral reflux outlining the entire upper urinary tract. With vesical outlet paralysis, a cystographic funneling of the posterior urethra is seen (Table VI).

In 200 cases of chronic enuresis we made cystometric observations to study alterations in the neuromuscular balance. Briefly, cystometry consists in gradual filling of the bladder with unit volumes of fluid during which time the increasing intracystic pressure is noted and from these volume-pressure data a curve is plotted. Inflammation of the bladder outlet posterior urethra or bladder walls often complicates the interpretation of the cystometric curve, but, as a rule, the neuromuscular as

well as the sensory (response to cold water in the bladder) status can be accurately determined. We found: (a) a half of all cases showed a normal curve; (b) a fourth were hypertonic (parasympathetic imbalanced) and (c) a fourth were hypotonic (sympathetic imbalance) (Table VI). Yet the information gained by cystometry has so seldom added to that obtained by other urologic methods that I have now practically discontinued these observations.

A cystourethroscopic examination is the next step. In most girls four years of age and over this can readily be accomplished without anesthesia. In boys over four years of age I have successfully used caudal block anesthesia or have employed urethral instillation of 10 per cent novocain hydrochloride solution. However, any child who is unruly or is caused pain should be given a general anesthesia. Still, the use of regional or local anesthesia in these cases has reduced the need of general anesthesia to about 10 per cent. Cystoscopy in patients with persistent enuresis has revealed almost every known lesion of the urinary tract; the outstanding findings include trigonitis, prostatitis, verumontanitis, neuromuscular disease of the bladder outlet, congenital contracture of the bladder outlet, congenital posterior urethral valves, urethral stricture, vesical stone, and infections of the upper urinary tract including tuberculosis.

Urethrotigonitis was the most commonly observed lesion in girls. Cystoscopically, it resembles in all respects this lesion in adult women and to which the term irritable bladder has been applied. The urethroscopic picture varies from chronic mucosal congestion to the production of granulomatous or cystic projections which are most striking at the bladder outlet where they give a marked irregularity to the outline of the orifice. In some instances, the mucosa is roughly granular; it may be intensely inflamed; sometimes there are adherent flakes of mucopus and submucosal ecchymoses are often seen. The urethral lesion always extends onto the anterior trigone. Occasionally, the entire trigone or even the adjacent bladder wall is similarly inflamed. In a girl of three years referred for examination because of enuresis, the bladder showed a generalized cystitis cystica. The cystic lesion extended into the deep urethra. The methods of treatment of urethrotigonitis in children are the same as in adults. Periodic urethral dilation and, usually, the local instillation of silver nitrate solution (1:500 to 1:100) have given the best results in

my hands. Treatments are first given at ten-day intervals with lengthening intermissions as improvement occurs. Often three or four treatments suffice.

Congenital obstructions along the urethra are the usual etiologic factors in chronic enuresis in boys. Of these lesions, stricture of the meatus is the most common. I have not observed enuresis due to phimosis, but, oddly enough, in some of our patients the enuresis was said to have followed circumcision. Next to obstruction, the most common causes of persistent enuresis in boys are prostatitis and verumontanitis which, in the past, have received practically no attention in this connection. The urethroscopic picture resembles that in adults; a granular, inflamed or edematous mucosa overlies the prostatic lobes and extends onto the anterior trigone. This condition is accompanied by a markedly irregular inflammatory swelling of the verumontanum. Occasionally, flakes of mucopus are adherent to the posterior urethral walls or to the verumontanum. In many of these cases the verumontanum presents the same deeply congested irregularly swollen, mulberry-like appearance regularly seen in adults as the result of excessive habitual masturbation. Moreover, in a large number of these boys the condition was due to masturbation (Table VII). In 4 boys I found papillomatous growths springing from the verumontanum and in a fifth, a large pedunculated tumor arising from the roof of the posterior urethra extended into the bladder outlet to cause ball-valve obstruction and irritation. Suprapubic removal of the growth cured the enuresis.

When the urologic examination is entirely negative as it is in about one-third of these cases (Table VII), further medical physio- or psycho-therapy can be pursued with the assurance that no serious or potentially destructive urologic lesion exists. With the acquisition of better cerebral control the child will ultimately cease wetting. However, these "functional" habitual bed-wetters can be identified and distinguished from the "organic" group only by urologic examination which establishes the integrity of the urinary apparatus in the former. There is a general feeling among pediatricists that all children will outgrow enuresis. Doubtless most children will stop bed-wetting, yet there are a certain and important number who, with advancing years, acquire a better cerebral control but, instead of wetting the bed, get up to void. Their etiologic urinary pathology remains and we, as urologists, see them in the second and third decades with

their persistent infravesical obstructions and large urinary residua

Having established the urologic diagnosis the lesion is treated by the same methods which would be employed were the patient an adult. In many instances obstruction must be removed, sometimes infection must be eradicated.

In enuresis which is due to neuromuscular disease, too much should not be hoped for, yet a girl of eight years with 10 ounces of residual urine was completely cured by suprapubic resection of the bladder outlet. She was followed up for one year postoperatively during which time the residual was never over one dram. In a boy of seven years who had been treated two years for enuresis, the tuberculous kidney was removed with restoration of control and a diminution of urinary frequency.

The urethral dilation coincident to the passage of the cystoscope has cured a few children. Yet this is not a psychic cure, in adults with chronic urethritigomitis, urethral dilation usually plays a prominent part in the treatment. Moreover, were cystoscopic dilation a uniformly successful method of psychotherapy our cures should be far more numerous (Tables IX and X).

SUMMARY

Enuresis is a symptom and not a disease. The diagnosis in children usually rests upon the occurrence of diurnal or nocturnal urinary incontinence. Although the condition is usually functional in a large number of juveniles it persists despite months of intensive medical physio or psychotherapy. Enurctic children in whom intensive therapy for two to four months is unsuccessful should be afforded the benefit of a complete urologic examination. In cases thus examined a third will show no demonstrable uropathology. They may be classified as functional and continued under the treatment commonly employed in enuresis. However two thirds of these cases will show pathologic changes in the urinary tract adequate to explain the symptomatology (Table VIII). One in six of this latter group will be unable to empty the bladder completely. The routine of the urologic examination we employ has been outlined. The treatment is based upon the etiology and corresponds to that employed in adults when identical uropathology exists. Urethral dilation will suffice in many cases, in others obstruction must be eliminated by surgical methods. If no lesion is found the enuresis may be confidently expected to disappear with advancing childhood.

A NEW INTRAVENOUS THERAPEUTIC AGENT FOR THE CONTROL OF PEPTIC ULCER

By H. A. Butman, M.D., L. J. Schultz, Ph.D., and L. A. VanKleeck, M.D.

Read before the joint scientific session of the Nassau County Medical Society and the Associated Physicians of Long Island, October, 1933.

The control of peptic ulcer has been a difficult problem before the medical profession for many years. Many theories have been advanced and many methods of treatment have been instituted. The desired results, from these various methods of treatment employed, have not been satisfactory, inasmuch as the complete alleviation of the suffering and symptoms of those afflicted has not been substantially accomplished.

Many theories as to the etiology of peptic ulcer have been defined;

1. The vascular or blood vessel theory.
2. The toxic or infectious theory.
3. The neurogenic theory.
4. The biochemical theory.
5. The traumatic theory.

The upper portion of the stomach receives blood supply from three large direct sources, the branches of which are few in number, tortuous in character, and anastomose very infrequently. In other words, they are essentially terminal vessels. Anatomically, therefore, it seems that the ulcer bearing area of the stomach normally has a scanty blood supply.

Brown¹ in his article on peptic ulcer states: "Disturbance of the blood supply to the area involved is of primary importance and may be due to various causes, *i. e.*, the formation of thrombi and septic emboli; development of small aneurisms or reduction of the size of the blood vessels; rhythmic contractions of the stomach with the resultant local ischemia of reflex nature; disturbance of the gastric nerve supply or traction upon the pylorus or duodenum in marked gastropnoia."

Circulatory deficiency or impairment, therefore, is perhaps the basic factor in the etiology of ulcer, and with this in mind we can truly say that ulcer is not a local disease of the stomach but rather a generalized systemic disturbance with local manifestations in the stomach or duodenum. We know, however, that many factors, as expressed by the other theories mentioned, undoubtedly play an important rôle in the development of the disease.

The similarity of the condition of thromboangiitis obliterans and peptic ulcer is evident, inasmuch as they both possibly begin as fissures, erosions or necrotic areas. It is logical, therefore, to assume that the same factor is responsible in both conditions.

While there is a variation in the histological findings, there is a definitely close similarity in the conditions of thromboangiitis obliterans and peptic ulcer. A condition known as venofibrosis has been described by Hauswirth and Eisenberg.² The symptomatology of the condition is similar to that of thromboangiitis obliterans and sclerosis. According to these authors the condition is not rare and occurs in persons between the ages of twenty and forty years. In the majority of the cases reported there appears to be an association with peptic ulcer. These authors state in the conclusion of their first paper on the subject that thromboangiitis obliterans begins in the veins, and the condition is not inflammatory; the inflammation associated with it is a terminal process occurring after the vessels have become thrombosed and devitalized. It was upon a theory similar to this, that we held the conviction that the condition of peptic ulcer should respond favorably to a employed in cases of on the basis of an local thrombosis.

The theory alluded to above is substantiated by the etiological similarity of the two conditions. That there exists a disturbance in the blood supply to the ulcerated area, tends to more conclusively indicate the logic of comparing the factors of these conditions, and venofibrosis along with other conditions in which there is an impairment in the circulatory system. It is also of interest to note from the histories and statements of those afflicted with either of these conditions (peptic ulcer-thromboangiitis obliterans), that there is a marked similarity in the nature and duration of the pain and suffering.

BLOOD STUDIES

The results of the blood studies in peptic ulcer disclosed no pathological changes in the sugar, urea nitrogen, nonprotein nitrogen, uric acid, cholesterol, calcium, or chloride content. The coagulation time indicated, in the majority of analyses, an increased tendency toward clotting. This would indicate a thrombotic tendency. These blood findings are closely parallel to those reported in thromboangiitis obliterans (Jablons,³ Meleney,⁴ Bernard⁵).

PRINCIPLES OF THE THERAPY

As has been stated many forms of therapy both medical and surgical have been offered

other than a pleasant tingling sensation in the tongue and lips. Hemorrhage which is a common complication of peptic ulcer is no contraindication to the employment of this therapy.

DIETARY ROLE

In the past, diet has played a paramount rôle in the treatment of this condition. We are all well acquainted with the classical therapy as has been so often described by Sippy,⁸ and we have no doubt that each régime has been employed extensively by all internists. It is not our purpose to condemn these régimes but rather to state that our experience over the past two years has convinced us that diet in uncomplicated ulcer, associated with this new therapy, while still of importance, permits from the onset of treatment, regular well-balanced and well-chosen meals of greater variety and amounts.

In our series, two cases due to severity of symptoms received alkalis by mouth in conjunction with the intravenous therapy. Two cases which were complicated by hemorrhage were placed on the Sippy diet for one week.

RESULTS OF TREATMENT

Our series consists of 22 cases, all of which have been diagnosed as duodenal ulcer, except 2 which were gastric. Of this group, 18 cases were studied under the routine as previously described. The remaining group of 4 cases could not be studied in like manner due to financial inability on the part of the patients. However, clinically, most of this group presented typical histories, as well as typical symptoms. Many of this latter group had been x-rayed in the past and either presented old plates which definitely identified the condition or presented written reports of the same from roentgenologists. Two cases as stated before were complicated by hemorrhage. Twenty cases were males and 2 females. The age incidence ranged from the youngest, a boy thirteen to the oldest, a man of sixty-five. The duration of the original complaint varied from three to twenty-five years.

The oldest of our group, a male of sixty-five, has had a duodenal ulcer of nineteen years' standing. To quote him, "During this time I cannot recall being without distress." He had been x-rayed and had been under classical treatment for the past ten years. He came under our observation during an acute hemorrhage, and for this reason no recent x-rays were made. The injections were started immediately during the bleeding stage. These were given every day for the first four days, and then twice a week, until twenty had been given. For the first week he was placed on

the Sippy diet and following this he was given the régime as described in this article. He became symptom-free after the sixth injection. It has been fifteen months since his last injection, he has gained 12 lbs. in weight and has had no return of symptoms. An interview with him three weeks ago revealed complete relief in every detail.

Perhaps the most interesting case in our series is that of a thirteen-year-old school boy, whose disturbance began three years ago. At the onset his complaints were belching of gas and slight epigastric pain one or two hours after eating, which would manifest themselves periodically every four or five months. Food would immediately relieve his distress. Pain gradually became a cardinal factor not only in severity but also in frequency and duration. When he came under our observation the pain had become so severe that in order to obtain relief he was forced to lay on the floor and exert pressure over the epigastrium. Roentgenological study revealed a very large duodenal ulcer. Intravenous therapy was immediately started and the usual dosage given. He responded most favorably being symptom-free after the second injection. Following his course of treatment he was re-x-rayed. This revealed the persistence of the ulcer but with apparent beginning healing. Symptomatically and clinically he was entirely well and up to one month ago has had no recurrence.

Another case record is that of a male, age forty-two years, who came under our observation following an attack of severe weakness, associated with passing of copious tarry stools. His past history was essentially negative, except for the fact that he suffered from mild attacks of so-called indigestion for many years. He gave no history of pain and stated that he had always been in excellent health. He was placed on the Sippy diet for one week in conjunction with the intravenous therapy. After eight injections he was symptom-free. During the interim between his fifteenth and sixteenth injection he complained of epigastric distress and vomiting associated with generalized abdominal pain. His pain, however, localized shortly and a diagnosis of acute appendicitis was made. He was operated upon and had an uneventful convalescence. Upon his return home he complained of epigastric pain. This was relieved by taking food, bicarbonate of soda, or a small amount of milk of magnesia. A gastro-intestinal series revealed a definite duodenal ulcer. Intravenous therapy was again started and he received a full course of twenty injections. Seven months later his re-x-ray was reported as a healed scar.

SUMMARY OF CASE RECORDS

CONCLUSIONS

Our results and the results of our colleagues who report favorably of over 100 cases have been more than gratifying, and we believe that this new method of treatment is worthy of merit and medical interest for the following reasons:

1. Circulatory deficiency or impairment is perhaps the basic factor in the production of ulcer. This may be brought about by various secondary causes, *i.e.*, trauma, infectious and toxic processes, chemical changes, disturbance of the gastric nerve supply, all of which aggravate and help toward the ultimate formation of an ulcer.

2. The intravenous injection of definite proportions of sodium citrate and chloride which has been buffered to the correct hydrogen ion concentration with a buffer salt, appears to be more effective in the treatment of peptic ulcer than the classical régimes which have been tried in the past. It approaches more accurately the supposed etiology of peptic ulcer. It promotes healing by:

(a) Improving the chemical or acid base balance of the blood.

(b) Improving both the direct and collateral circulation to the ulcer bearing area of the stomach and duodenum thereby lessening the tendency toward capillary stasis or venofibrosis with consequent malnutrition of gastroduodenal mucosa.

(c) Improving the tissue resistance to digestion of the same by the gastric secretions.

(d) Improving the general circulatory system throughout the body with resulting increased resistance to systemic disease.

3. All cases in our series were symptomatically cured.

4. Ulcer complicated by hemorrhage is no contra-indication to the employment of this form of therapy.

5. The use of this solution permits from the onset a more liberal diet for the patient, except in those cases which are complicated by hemorrhage.

6. Our experience has proven that the solution and method of its administration are absolutely safe inasmuch as we have experienced no untoward symptoms or reactions in our entire series.

7. The use of alkalis by mouth are unnecessary in the average case during treatment by this intravenous method, except where symptomatology persists in being severe and then only from seven to fourteen days or at the discretion of the physician.

8. This form of treatment should be given routinely two or three times a week depending on the symptomatology. Twenty-four injections constitute a course following which we recommend that an injection be given every two to four weeks for a period of at least twelve months. By so doing, healing is maintained and the chance of recurrence is minimized. This we feel is substantiated by the

fact that those cases in our series which were re-x-rayed showed a definite tendency toward healing which we felt would continue to a full healing state under prolonged treatment.

9. Classical treatment requires bedrest for those individuals afflicted with uncomplicated ulcer until such time as a maintenance diet will permit them to return to work. This to the majority of ulcer patients is a hardship primarily due to the financial ability of the majority of these cases to afford the time. This new method of treatment permits a maintenance working diet at the onset which, to these patients, is of paramount importance.

10. No positive statement as to permanent cure can be made at the present time but at a later date and after longer observation of these cases a definite statement may be forthcoming.

THIS AND THAT

An investigation to find what the average family pays for medical care was made by the Metropolitan Life Insurance Company among the members of the families of its own field force. It found that the average annual expense per family was \$104.20. Among families receiving from \$1,200 to \$2,000, the expense for medical care averaged \$63.40. Among those getting \$2,000 to \$3,000, it averaged \$80.38. Those getting from \$3,000 to \$5,000 paid \$110.54, those getting \$5,000 to \$10,000 paid \$167.77, and those getting \$10,000 and over paid \$270.34. These figures are less than those reported by the survey of the Committee on the Cost of Medical Care, whose estimates for the same incomes were \$66.81, \$94.84, \$137.92, \$249.35, and \$503.19 respectively.

Electrical waves, that interlace like the ripples on the surface of a pond, occur in the gray matter of the brain and form the physical basis of our thoughts, according to the picture put forward by Prof. E. D. Adrian of

Cambridge University before the recent session of the British Association for the Advancement of Science, as reported in the *Diplomat*, organ of the National Board of Medical Examiners.

The activity of the nervous system is essentially rhythmic, consisting of a series of rapid alternations between resting and active states. There is, however, a difference between the electrical disturbance which travels as an impulse along the nerve fiber and the rhythmic electrical changes in the gray matter of the brain. The former spreads along the fiber as a monetary wave—a brief impulse followed by a brief interval of rest and recovery. In the cerebral cortex, on the other hand, instead of the abrupt "spikes," as observed in a record from an active nerve fiber, there are more gradual large electric oscillations which form a series of waves of smooth contour. Such variations can be automatically registered by delicate electrical instruments.

Health Audits

There are throughout the country a number of lay agencies which undertake periodic health examinations, often called health audits, by means of clinical and laboratory investigations by duly qualified physicians and their technicians. They make yearly contracts for this service to be rendered at regular intervals, with individuals as well as with corporations for the benefit of their employes. Formal reports are rendered with instructions relative to mode of life, diet, and exercise, but medicinal treatment is not instituted.

It is generally believed that such lay agencies are practicing medicine unlawfully and this belief has consistently been that of eminent lawyers.

The *A.M.A. Bulletin* of January 1934 quoting *Minnesota Medicine* prints an article of much interest in this connection. It appears that a lay agency conducting "health audits" sought an injunction restricting the Minnesota State Board of Medical Examiners from in any way interfering with the conduct of their business. The business consisted of periodic urinalyses and blood pressure tests. A licensed physician was in the employ of the plaintiff. A charge of ten dollars a year was made to the "subscriber." The District Court of Hennepin County sustained the demurrer interposed by the State Board of Medical Examiners, and among other things stated:

"Advising the subscriber for a fee as to certain improved habits of diet, exercise or living, although not accompanied by any medical prescription or treatment, is a violation of Section 5717, (Medical Practice Act)."

The Court also held that the plaintiff was engaged in the diagnosis or analysis of the condition of human health and this constituted a violation of the Basic Science Law. The Court stated that this law intends:

"That the patient shall be the patient of the licensed physician, not of a corporation or layman. The obligations and duties of the physician demand no less. There is no place for a middleman."

This order of the District Court was affirmed by the Supreme Court of Minnesota in a strongly worded opinion, to wit:

"1. The plaintiff, a layman, in conducting 'health audit' for a fee for which he furnishes his subscribers with the results of urinalyses and blood pressure tests and either himself advised, or passed on to the subscriber advice from the pathologist who made the urinalyses, as to whether the results showed a normal or abnormal state of health and whether the subscriber should see a physician, in some cases advising as to diet, exercise, and habits, was practicing medicine unlawfully in violation of Sec. 5717 Mason's Minn. S 1927.

"2. In so doing he is practicing the science of healing in violation of Sec. 5705 Mason's Minn. S 1927, which defines the science as including the diagnosis or analysis of the condition of human health.

"3. Plaintiff's contract with his pathologist was illegal and in violation of statute and the public policy of the state."

It is probable that the laws of other states justify similar opinions and if so, this decision should be a strong incentive in restricting medical practice to duly licensed members of the medical profession.

"Cold Soup"

Former Governor Alfred E. Smith recently remarked that our many-lettered relief program resembles the result of a game of anagrams played with the alphabet noodle soup by one of the absent-minded professors of the "brain trust." That is humorous when the "noodle soup" grows cold, and the poor recipients of relief find that it is insufficient. The Nassau Medical News, organ of the Medical Society of the County of Nassau, makes some pungent observations on this situation.

The alphabetical relief organizations, it seems, have often put non-medical appointees

in charge of the medical relief work, a piece of stupidity sure to be injurious to both doctor and patient. The result is, as the Nassau editor observes, that "there is throughout the nation a rising tide of indignation on the part of the profession against lay dictatorship and against rules and regulations, interferences and meddlings, which result in bad medicine and the neglect of the best interests of their patients."

Imagine the feelings of a doctor dealing with some understrapper who returns his bills with childish criticisms and cuts the amount to less than his actual expenses. He is asked why he failed to state the sex of Mary Jones, and is instructed to violate the confidence of his patients by disclosing on the public records their exact ailments and treatments. He soon comes to feel that he or some other physician is better qualified to oversee medical relief than is "some clerk, himself on the relief rolls, whose knowledge of medicine was derived by careful listening to the Indian medicine man shows over the radio."

It would be only natural if the doctors tired of this stupid blundering and gave up the relief work, but the medical profession encounters so much stupidity and worse all the time, and is so used to giving its services freely to the needy, without money and without price, that it will no doubt continue. But the work will be hampered, damaged, and the ones who will suffer will be the indigent, who need all their available health and strength to cope with the crisis they are facing. The Government is aiming to provide them with the necessities of life, food, shelter, clothing, and is paying for them. Medical care is also a necessity of life, and, as the Nassau editor concluded strongly, it should be provided through existing channels and be paid for at current minimum rates.

Wasting the Doctor's Time

Two classes of patients waste the physician's valuable time. One is made up largely of the fair and fragile sex; the other of the strong, silent, masculine persuasion. The time wasters in the first class are the ones filled with imaginary aches and pains and run to the doctor every few days, seemingly to get material for conversation at the bridge club. The con-

tinual discussion of operations and symptoms when ladies meet was once described by a wag as an "organ recital." Reputations of local doctors are made and unmade at such meetings, and it takes a brave physician to tell a garrulous patient that nothing is wrong with her but her imagination. Her little rapier would be busy at the next bridge meeting. But he emits a mental sigh when he sees her enter his office door.

The other class are exactly the opposite. They are the men who "never give in" to an illness—until it is too late to do anything. They are "too busy" to see a doctor till past help. Even if friends persuade them to take medical advice, they pooh-pooh it, refuse to take any medicine, or go to a hospital, until it is almost time for the undertaker. "Never took a drop of medicine in my life," they say proudly, "and I'm not going to begin now!" Then the doctor is blamed for the result. With both classes, his best efforts are wasted, and he must often wonder why the two, the doctor-crazy and the doctor-shy, could not strike an average and gain sense and health at the same time.

Thorns Crackling Down the Ages

The laughter of fools, so we have it on the highest authority, is "as the crackling of thorns under a pot." If we bend our ear to the echoes that float to us down the long corridors of time, we shall hear the crackle of the derisive hoots and yells of mirth that have greeted every advance in the art of healing.

We do not need to go any farther back than the days of our own Oliver Wendell Holmes for an illustration. Holmes, as everyone will recall, pointed out that puerperal fever was carried from patient to patient by the unclean hands of the physician. His words were met with hostility and ridicule; the crackle of the thorns rose to such a pitch that there was danger that his great discovery would go for naught. Then within five years what Holmes had stated on paper was proved true in practice by Semmelweis of Vienna. He forced his attendants to wash their hands in chloride of lime, and the maternal mortality in his hospital fell from 9.92 to 1.27 per cent. He had anticipated Koch and Pasteur in showing that infection caused blood poisoning; he had anticipated Lister's idea of antiseptics.

What happened? He was laughed at, discredited, derided. He was, in fact, hounded out of Vienna, and, broken in spirit, he went to Budapest, where the strain of the senseless persecution drove him insane and, in a few years, sent him to his grave.

The thorns were a crackle long before the time of Holmes and Semmelweis, however. Think of the temerity of an anatomist like Vesalius, who had the hardihood to assert, in the 16th century, that human beings did not have the same muscles as dogs and monkeys, and that womankind did not have the two-horned uterus of the brutes. He thought it better to dissect human bodies, rather than those of animals, to learn the secrets of the human frame. Absurd! Ridiculous! The crackle became deafening. Those who did not deride him thought it kinder to ignore him like a naughty child, and at thirty, tired of his petty persecutors, he threw his writings into the fire, gave up anatomy, and became a court physician to Charles V.

The guillotine, too, has played its part in the fool's comedy. The French chemist Antoine Laurent Lavoisier is associated in medical history with the establishment of the foundations on which the modern science of chemistry rests. His zeal for aiding and reforming the social and economic conditions of the people of France brought him into association with the farmers-general, who fell under the disfavor of the revolutionists, so his fate was sealed. It was a bit hard to charge such a man with any crime; Marat, therefore, accused him of stopping the circulation of air in the City of Paris! A sage comment on his fate was made by Lagrange, who remarked that it took only a moment to cut off the head that a hundred years would not suffice to reproduce.

The campaign even now against vaccination makes it easy to believe that in its early days laws were passed to prohibit it. Like other prohibition laws, however, they were overwhelmed by a popular wave of disregard and nonobservance, and the thorny crackle of mirth died down to the faint manifestation that we hear now and then from the genial George Bernard Shaw and others of a radical turn of mind.

Nothing, however wise and beneficial, seems to escape this idiotic and moronic opposition. We might think that the discovery of anesthesia would be hailed by everyone who had

witnessed the frightful agonies of surgical operations or who had heard the piercing screams of women in the pains of childbirth. Not at all. We read in "Mystery, Magic, and Medicine," by Dr. Howard W. Haggard, whence these facts are gleaned, that the Scottish clergy (men, of course) kindly pointed out that the scriptures plainly said that "in sorrow thou shalt bring forth children," so it was wicked to try to prevent it by anesthesia! But a resourceful Scottish physician, Dr. James Simpson, who discovered the anesthetic properties of chloroform, reminded the clergy that when Eve was born, God cast Adam into a deep sleep before taking the rib, so anesthesia was warranted by scriptural example.

Even Banting, it seems, had great difficulty in persuading the authorities at the University of Toronto that he was doing anything worth while, and nearly had to halt his work on the eve of his epochal discovery of insulin, which has revolutionized the treatment of diabetes. Walter Reed's name is made immortal by his work in the prevention of yellow fever, but the key fact, that the disease is carried by a mosquito, the *Stegomyia fasciata*, was advanced 19 years previously by Carlos Finlay of Havana. Finlay was regarded as a visionary. Mosquitoes! A good joke! Think of the thousands who died in those 19 years because fools had to have their laugh.

The worst of it is that the idiotic crackles will no doubt continue to the end of time. Every scientist must face them, fight them, conquer them. The hopeful side of it is that never in the history of the world has the human mind been more open to new truth than it is today. The tendency to take new discoveries seriously is growing. The crackle of the thorns continues, but it is less raucous. It happens more and more often that the scientist has the last laugh. And he who laughs last, laughs best.

Cold Cures and Cold Cash

Our common enemy, is the common cold, according to a new little volume small enough to put in your pocket. Common as it is, however, it is uncommonly hard to handle. The old English doctor, when asked what he used for a cold, replied: "I use two dozen soft linen handkerchiefs," and one of

our own leading authorities today, Dr. Alphonse R. Dochez, when asked what he did for his own colds, answered: "I stay home, in bed." Both replies are confessions that this pestiferous little malady has the experts more or less baffled. Hence, the value of a handy volume about it, prepared "in consultation with eminent physicians." The editors of *Fortune* are the authors, it is titled, "Our Common Enemy: Colds," and it is published by McBride.

And a cold may not be such a little matter, either. It is complicated by the fact that 50 per cent of all disabling diseases start with a cold in their early stages. Scarlet fever, tuberculosis, meningitis and measles "are all fond of playing this practical joke on the medical profession." And what is more, Dr. Dochez is quoted as saying that "the more thorough study of this disease begins to indicate that it may be the keystone of that complex of ills, the causative agents of which gain entrance to the body by way of the upper respiratory tract."

The cause of the cold is obscure, but experts are quoted as agreeing with the German Professor Doctor Kruse, who announced in 1914 that it is caused by a "filtrable virus," visible under the most powerful microscope. A dissenting opinion is cited from "fiery little Anna W. Williams, M.D." of the New York Health Department, who is willing to blame the filtrable virus in some cases, but thinks most colds are instigated by some such disturbing factor as wet feet, an emotional upset, or not enough vitamins.

What to do, then? That is where we come down to "brass tacks." To "stay home, in bed," is not so easy for everybody, and the sufferer puts the problem up to the family physician, who is expected to prescribe a treatment that will cure the cold. Well, as we all know, cold vaccines have long been in use, and the medical laboratories stand ready to supply them. But authorities disagree on their values. Large corporations, too, which try to keep their workers fit, have tried inoculation, and "it is hard to discover what results, if any, these companies have had," we are informed. Indeed, "what can be learned is almost entirely negative." The New York Telephone Company, the New York Edison Company and the Curtis Publishing Com-

pany, however, give inoculations to those employees who wish it and believe that they are more helpful than not. Ultraviolet rays and chlorine gas have also had their advocates, but are regarded with more or less skepticism by the medical profession.

Diet has had intensive study. Alkalies like bicarbonate of soda have been prescribed, on the idea that colds are due to an acid condition of the body. Certain general rules for eating are unanimously accepted by cold students, so the authors of this volume report. To ward off colds, they agree, one should get plenty of vitamin A, found in cod liver oil, prunes, spinach, carrots, "and other depressing foodstuffs." Also enough vitamin B, which corrects acidosis and occurs in whole cereals, fruits, nuts and vegetables. The experts recommend, too, at least six full glasses of water daily and very little candy and sweets.

The practical proof of the value of this regimen appears in the statement that it is "the cornerstone of the New York Federal Reserve Bank's extremely effective anti-cold measures." The diet is supplemented by sunbaths and inoculations, snufflers with any fever are sent home, and, all in all, "the bank has come closer to whipping the cold problem than any other large office downtown." In a recent grip epidemic, the bank's absenteeism due to colds showed a peak of only 7 per cent, while the rest of Wall Street district was having peaks of 15 to 25. The Federal Reserve diet is alkaline, nonfatty, non-carbohydrate, strong in fruits, vegetables, and fluids.

The snufflers and sneezers should be bodily ejected from school, office, theater and restaurant, sent home and put to bed, and until they are, "the great American people will continue to catch some 100,000,000 colds every winter," we are assured. The cynical old medical joke is that "An untreated cold lasts 14 days, while a treated cold can be cured in a fortnight." While still on the humorous side of the question, the authors quote the old New England epitaph:

"Here lies our wife Samantha Proctor,
She ketched a cold and would not doctor,
She could not stay, she had to go—
Praise God from whom all blessings
flow."

Now we come to the "cold cash" part of the cold problem. The physician may not be able to find a cure for colds, but the advertising pages are crowded with them! One of them paid its stockholders \$6,000,000 in four years, and the last-published annual report showed \$3,704,606 net profits for the year. The ethical manufacturers, too, have their remedies, but with milder claims, such as "Indicated in some cases. . . . Has sometimes proved of value. . . . May, when properly prescribed." One strictly ethical house has 150 products more or less directly designed to combat colds.

Almost all the cold remedies, we are assured—ethical, unethical, and even doctors' prescriptions—contain much the same ingredients and do much the same jobs. A country druggist may take a doctor's prescription that has proved helpful, put a catchy name on it, with a fancy label, start an advertising campaign, and in a few years roll in wealth. The last half of the book gives a review of the cold remedies that flood the market and make their manufacturers rich. Some of them you sniff, some you suck, some you gulp, some you swallow, some you rub on, and at the end of the fortnight the cold departs and the gullible victim is ready to write a testimonial.

Patients Who Swindle the Hospitals

The tidy sum of \$600,000 was lost to the taxpayers, "through the grafting of people who have lost all sense of civic responsibility," in the three general acute hospitals of Bronx County in 1933. That is the amazing verdict of the committee that has been investigating the financial resources of patients applying for free treatment at the Morrisania City Hospital. The committee was made up of Dr. Nathan B. Van Etten, Medical Director of the hospital, Dr. Frederick Flynn, President of the Hospital, and Dr. William Klein, President of the Bronx County Medical Society, certainly a personnel to inspire confidence in the findings. The Bronx County Society contributed \$500 toward the expense of the investigation and the medical staff of the hospital contributed more than \$600.

The cheaters who get undeserved free treatment at the public hospitals do not cheat the

taxpayer only. They cheat the doctors who give their services free to the public hospitals, and they cheat the indigent poor who cannot find room in these overcrowded institutions. If refused free treatment, they would soon be found in the waiting rooms of the regular practitioners, where they belong.

A committee last year figured the value of the free services given by the physicians on the staff of one city hospital in the Bronx at \$1,347,155 a year, and as the Bronx has two other city hospitals of about the same census, the total for the three would come to over \$4,000,000. We must keep it in mind, too, that the doctor is also a taxpayer, so he takes the loss in his practice, in his free service, and in his tax bill. And what is true in Bronx County is no doubt true, in greater or less measure, throughout the State, so we have a situation here well worth our attention.

The agitation started in April, nearly a year ago, and the committee engaged a credit service bureau to study the cases of 1,000 unselected patients applying for hospitalization. Each patient, when applying, was asked to answer a questionnaire which has been for several years in successful use at the Buffalo City Hospital. It requires not only the patient's name and address, but his occupation, earnings, rent paid, arrears, number of rooms and landlord, for present and last previous residence, fraternal affiliations of himself and others in the family, "children elsewhere," church, pastor, employer, property, mortgages, taxes, insurance, debts, aid received from agency, lodge, union, compensation, etc. The applicant is also required to promise that if able at some future time, he will pay for the present treatment.

Investigation by the credit agency revealed that 583 or less than 60 per cent of the 1,000 applications, were really unable to pay, 118 were able to pay, 107 were able to pay with the help of the family, 85 had given false addresses, and 107 were "possibly capable of paying a physician or of obtaining credit from a physician or of paying minimum rates in a semiprivate institution."

Taking these findings as a fair sample of conditions at the three city hospitals in the Bronx, the committee figures the total of the huge hospital swindle at \$600,000. The physicians who freely attend these grafting patients, says the committee, "defraud them-

selves and practitioners who have no hospital connections by complaisantly serving these patients with the real luxuries of excellent medical care without protest and in a spirit of submissive recognition of the futility of trying to do anything about it." This is a mistaken attitude, we are assured. Physicians should cooperate "in a sincere effort to correct these abuses."

It would be hard to put more wisdom into fewer words than the committee does when it remarks: "If the admission of unworthy applicants can be controlled, overcrowding will be relieved, the poor will have better treatment, nongovernmental hospitals will be helped, and private practitioners will have more patients, and the city of New York will save a very large sum of money."

VICTORY OVER T. B. NOT YET WON

Leaders in the fight to conquer tuberculosis warn us that any attitude of self-satisfied complacency over the fine record made thus far may have grave results. There must be no relaxation, no let-up, in the grim struggle. The *News Letter* of the Suffolk County Medical Society prints a warning that while tuberculosis has lost its preeminent position as the master killer, there is no justifiable reason for anyone to be satisfied with the present situation.

It has been estimated that the annual tuberculosis cost in the United States approximates one billion dollars. Almost 315 million dollars are wasted annually through loss of future earning power caused by death, 300 millions more through loss of wages, and an additional 150 millions for treatment. To this colossal outlay must be added the incalculable cost in direct and indirect misery and suffering chargeable against the Great White Plague.

No one appreciating these facts can complacently view the present-day tuberculosis problem. And this, even in the face of a net saving of at least 1,100 lives a year due to sanatorium care of tuberculosis cases, and the further fact that of the 800,000 persons who have passed through the sanatoria in the United States during the last ten years, nearly 600,000 are still alive.

It should be observed that, in spite of the really great strides which have been made against this malady, much more needs to be done.

... protection of the
... um districts, and
... hygienic living
have played important parts in the great fight thus far made. However, the situation now demands, and indeed has demanded for years, that the individual citizen has a clearer conception of his personal duty in the fight which he now possesses.

Why not set up an active credit agency in every hospital to examine the financial responsibility of applicants for free treatment? That is what the committee urges, and it would seem from these figures that it would more than pay for itself. Besides, it is clear as daylight that these grafters are suffering from a moral illness that is as serious as any physical malady that brings them to the hospital door. Their disease of the soul needs treatment, too, something sharp and decisive, to awaken them to a sense of justice and common honesty. Conditions in Bronx County are evidently in for a housecleaning, started by the County Medical Society. A statewide campaign along similar lines by the county societies might have salutary results.

The common danger signals of tuberculosis are: A continuous tired feeling, loss of weight, a persistent cough, indigestion, pain in the chest, and spitting of blood. These signals do not necessarily mean that tuberculosis has developed, but they call for an immediate professional check-up.

It is at this point where thousands of persons fall down. Tuberculosis in the home is thus spread, particularly to children; and the vicious circle remains unfortunately intact.

When the average citizen fully realizes that tuberculosis is a preventable disease, that it is not directly inherited, that it is acquired by direct transmission of the tubercle bacillus from the sick to the healthy, and thus recognizing early symptoms, takes the necessary steps to prevent the spread of the infection, the death rate from tuberculosis will definitely and satisfactorily diminish.

Public health, represented by clinics and sanatoria, has and will continue to do much, but personal cooperation by way of early recognition and control is the next step forward.

ELECTRICITY USED BEFORE CHRIST

Electricity was used therapeutically as early as the third century before Christ, Dr. Leo Pariseau, radiologist of Montreal, told the Annual American Congress of Radiology, reports the *Diplomate*. Doctor Pariseau traced the history of this early use of electricity down to the present. Doctor Pariseau said that first mention of this use of electricity was found in Aristotle's book, *De Natura*. The electricity from a finny monster called the torpedo fish, whose live body was said to possess qualities of healing pain. From Aristotle down to the sixteenth century various writers told of the same fish, now known as the electric ray. The word electricity, however, was not used until William Gilbert, physician to Queen Elizabeth, coined it.

Correspondence

Anonymous letters will not be noticed. All communications must carry full name and address of the writer, but these are omitted on request.

To the Editor:

As one in the ranks of the Medical Society of the State of New York, I wish to congratulate the editors on the new format of the Organ of our Society. The smaller page and general arrangement of topics are excellent. The type in the first three issues was too small to permit easy reading but I am pleased to note from your announcement that this is to be corrected in the next issue. Its size at present is convenient and the reading material selective. I trust the Editors will continue this policy and not permit the JOURNAL to become too large and bulky.

JAMES M. O'NEILL, M.D.

To the Editor:

One of the most serious complaints received by this Authority, is the practice of rebating or the giving of commissions by the retail pharmacist to the physician and the latter's acceptance of same.

While it is perfectly ethical and considered as no violation of the Retail Drug Code for a retail pharmacist to supply a physician with merchandise below his cost, the gratuitous payment of any sum by the pharmacist to the physician based upon the number of his prescriptions filled, is not only highly unethical but constitutes a definite violation of the Code of Fair Competition for the Retail Drug Trade.

Our purpose in writing to you, is to secure the necessary publicity through such medium as may be at your command, with the assurance that your doing so will render a most distinctive service to our beloved profession.

We feel certain that you will agree with us that such practices, while not reflecting a general condition, show an utter disregard of moral or ethical standards and that every effort should be bent toward the elimination of same.

May we therefore ask that you be kind enough to give this condition the publicity it deserves.

Should you desire any additional information, we shall be pleased to give it to you upon request.

RETAIL DRUG CODE AUTHORITY FOR N. Y.
(Signed) Samuel A. Weiss,
Executive Secretary

To the Editor:

Permit me to add my congratulations for what you have done to the Journal to those of others. From its size, which is more convenient; its cover, which is more distinctive; its better quality of advertising, which reform was needed; to the terseness of the original articles and the editorials, the reading of the magazine has become a pleasure and not

a duty. I do not call for a larger type, however, but that seems to be requested by many.

There was a small note in a corner of the last issue which reminds me of a controversy that I recently had with the Public Service Commission and the Westchester Lighting Company (our local branch of the Consolidated group). The note was about residential telephone charges. I have paid residential rates all along, but I am glad to see our Society call attention to it.

About eighteen months ago a so-called reduction in electric rates was "ordered" by the above P.S.C. I did not note my bills to be any lower, but I got them on buff paper instead of the former white. After a while I woke up to the fact that I was now paying commercial rates—the same as the former domestic rates, hence no reduction (such as it was).

Getting no satisfaction from the local lighting company, I wrote to the P.S.C. They sent as their investigator an amiable gentleman from the Westchester Lighting Company! I was shown that the P.S.C. had "ordered" commercial rates for all physicians—office in home or elsewhere. This notwithstanding that I had installed a power line for the office appliances. Since another physician has gone over the same road.

As I have often wondered—what public service does the Public Service Commission perform? I have some dark thoughts which I shall not commit to paper. It seems what is sauce for the goose—the Telephone Company—is not sauce for the gander—the Electric Trust. Incidentally, I think the telephone rates are quite fair.

JOHN PHILIP TOLAND, M.D.

To the Editor:

In the "Journal" of Feb. 1st, an editorial comment on sterilization does not quite tell the whole story. May I be allowed to continue the discussion somewhat further?

Darius Green was the humorous product of the mind of J. T. Trowbridge who showed his genius also in other writings. No doubt he would have allowed Darius to successfully negotiate the air had he confidence the public mind would discredit the act.

Edgar Allen Poe, entertaining the same scepticism, thought it wise to frankly label his eight passenger air voyage across the Atlantic "A Balloon Hoax." Was he less a genius as a writer, or did he hesitate to deceive his readers.

When the scientist asked Capt. Nemo, navigator of the "Nautilus" the source of his motive power, he pointed through a porthole and replied, "Electricity," a simple anticipation in the imagination of a genius, the development of power in the future internal combustion engine and storage battery.

Madison Grant says "to imitate or adopt

what others have invented is not genius but mimicry." Consequently with Trowbridge a genius, the Wright brothers were imitators.

Men marvel at genius and believe it a very desirable human quality though Havelock Ellis has observed that about five or six per cent of men of genius have lacked sanity.

Tennyson in "Locksley Hall," with prophetic vision anticipated what occurred more than one hundred years later over France, in the following sentence.

"Heard the heavens filled with shouting
And there rained a ghastly dew
From the nation's airy navies
Grappling in the central blue"

Such minds as referred to offer no menace to civilization and do not suggest sterilization. I am more afraid of a legislator who promulgates a law making it legal for a doctor to prescribe a pint, and making him a criminal if he prescribes seventeen ounces. Criminals are not made by law, neither should sterilization become a question of sentiment. Neither does it contemplate criminology. The question of behavior may be a criterion but the profound issue is the survival of American civilization. We are certainly living in a much too sentimental age. The unfortunate from any cause appeal strongly to our sympathy. Thomas Jefferson was influenced by this instinct when he wrote in the Declaration of Independence "all men are created equal," a very mistaken and erroneous idea.

Lothrop Stoddard says: "The idea of natural equality is one of the most pernicious delusions that has ever afflicted mankind. . . . Nature knows no equality. No two individuals are ever precisely alike. . . . The innate differences between members of a low grade savage tribe are as nothing compared with the abysmal difference between an idiot and the genius who coexist in a high grade civilization."

If we should bend our efforts to increase the birth rate among the genius producing class, while perhaps

scuties. While among the Spartans, it failed signally under moral criticism when undertaken in central New York. Under serious consideration, man has only two methods of choice that are practical. One is segregation and the other sterilization.

Who Middle Ages
to di ing in death,
life of the prog-
gress s of society
eliminated them, leaving for the perpetuation
of the race the stupid and brutal.

Who would think of commending the civilization of Spain of today? It is said the Inquisition condemned to the stake or imprisonment an average of one thousand persons annually. The condemned were not among the lower classes. No doubt they were among the class that should have been preserved for the evolution of a better race. A similar elimination of brains and intelligence took place in northern Italy and in France where hundreds of thousands of desirable Huguenots were murdered or driven into exile.

This method of decimating the wellbred and undermining a civilization has proven all

too successful in past histories. It served to maintain, so to speak, a balance of power in the undesirable class. The same result is now unconsciously threatened through our methods inspired by sympathy, of showering attention on the unfortunate victims of ill breeding and at a tremendous expense, housing them in attractive almshouses, asylums, penitentiaries, state schools and other institutions, so carefully named as not to offend an esthetic sense.

It is said if you touch a man's pocket book, you touch him in a vital spot. At no time in the history of America has this been more real than at the present. Taxation, enormous now, bids fair to become prodigious. The government is even now shaking the tree for billions of dollars to put in the budget. One out of every twenty of our population is receiving pay for his part in public service.

In the State Public Health Report for 1932, Dr. Parran estimated adequate care for syphilitic cases for one year would cost the state sixteen million dollars. At the present time, we have nearly sixty upstate clinics and are admitting new cases at the rate of five thousand annually and administering about one hundred and fifty thousand treatments. In state institutions, there are approximately two thousand patients suffering from general paresis, the annual cost of care of these cases is approximately eight hundred thousand dollars. The cost of equipping state institutions is approximately four thousand dollars per capita. This is for general paresis as reflected in cases of syphilis. The facilities of state institutions for the care of cases of general paresis are valued at about eight million dollars.

The foregoing figures represent only a small part of the economic loss and expense to the state from syphilis alone. We all know that syphilis is one of the greatest underlying agencies for the destruction of civilization.

That a spirit of rebellion is growing in the hearts of the tax-burdened people in some sections of the country is evidenced in sterilization laws which have been enacted in many of our states. There are objectors, of course, but they are not the ones who are taxed to the loss of their farms and property to support these institutions.

One fault is, sterilization is not commonly understood. It should be explained that the operation is not to emasculate.

Civilization is complex. It involves humanities which cannot come out of ill bred, uncultured and tax-oppressed people. Those conditions breed jealousy, discord, racketeering, murder and war.

If our civilization is to succeed and last longer than others that have crumbled in the past under no greater stress, attention had better be centered upon the golden rule in the science of Biology, rather than the shifting golden dollar of the present day. A country of prisons full of Capones, penalized for a time only to be released to breed more of their kind, and also as vicious a type of kidnappers and racketeers, constitutes a deplorable legacy to hand down to posterity, only to undermine our civilization.

G. MASSILLON LEWIS,
Vernon, New York.

Society News

Committee on Legislation

Bulletin No. 5

Since our last bulletin the following bills have been introduced:

Senate Int. Number 505—Berg, to amend the Education Law by extending to six months after May 17, 1934, time for applying for license to practice physiotherapy. Referred to the Education Committee.

Senator Berg has carried this bill for several years. He wishes to open the examination for physiotherapists on the ground that several clients of his could qualify but for some reason or other they were unable to make application during the time allotted by the law.

Senate Int. Number 514—Palmer; Assembly Int. Number 626—Cornaire, to amend the Vehicle and Traffic Law by providing exemption in favor of ambulances shall apply only to ambulances used exclusively to carry sick or injured persons. Referred to the Internal Affairs Committee.

Senate Int. Number 559—Wald, to amend the General Municipal Law by providing no person in charge of ambulance maintained by hospital subsidized in whole or part by public moneys shall refuse to answer call therefor, penalty also made to apply to person by whom call for ambulance is received or to whom call is communicated, and relative to defense to prosecution. Referred to the Cities Committee.

Senate Int. Number 566—Berg, to amend the Education Law relative to entrance regulations to professions by providing Regents may, where practice is a prerequisite to license, receive evidence of such practice in whatever state or country applicant may have been engaged in. Referred to the Education Committee.

Senate Int. Number 568—Esquirol—Assembly Int. Number 695—V. C. Lewis; adds new sections to the Public Health Law for control of state tuberculosis hospitals by Health Department and relative to administration, powers of superintendent, appointment of consulting staff and aid to county hospitals. Referred to the Health Committee.

Senate Int. Number 569—Esquirol; Assembly Int. Number 694—V. C. Lewis, to amend the State Finance Law for fiscal supervision, estimates, accounts and vouchers of the three tuberculosis hospitals in Health Department. Referred to the Finance Committee.

Senate Int. Number 571—Patri, adds new section to the General City Law, prohibiting milk and cream inspections outside the state by the state and cities at state or city expense. Referred to the Cities Committee.

Senate Int. Number 577—Byrne; Assembly Int. Number 754—McDermott, adds new section to the Education Law for governing sale

and distribution of lye and other caustic substances in containers for household use. Referred to the Education Committee.

This bill passed one House last year but got lost in the shuffle at the end of the session in the other House.

Senate Int. Number 596—Esquirol; Assembly Int. Number 782—Moran, adds new article to the Public Health Law for licensing bakers and dealers in bread and pastry. Referred to the Health Committee.

Senate Int. Number 621—H. L. O'Brien, to amend the Workmen's Compensation Law by making provision for presumption as to cause of an occupational disease, apply also to employees coming in direct contact with any of the substances mentioned in schedule. Referred to the Labor Committee.

Another occupational disease bill.

Senate Int. Number 622—Wald, to amend the New York City Inferior Criminal Courts Act by providing court on motion of defendant shall order making of one or more blood grouping tests, results of such tests to be received in evidence. Referred to the Codes Committee.

Assembly Int. Number 622—Wadsworth, adds new section to the Public Health Law for encouraging production and sale of clean, fresh and natural milk, as well as pasteurized milk, derived from healthy cows, production and sale not to be prohibited or burdened with unreasonable restrictions by state or local health officers, and requiring Public Health Council to prescribe reasonable standards and regulations. Referred to the Health Committee.

Mr. Wadsworth says that he has introduced this bill in the interest of the small farmers in his vicinity who could sell raw milk but would find it financially difficult to pasteurize it.

Assembly Int. Number 716—Potter, adds new section to the Lien Law for liens of hospitals for taking care of persons injured as result of negligence of another person or corporation. Referred to the Judiciary Committee.

This is one of the hospital lien bills carried by Mr. Close last year.

Assembly Int. Number 741—Coughlin, Workmen's Compensation Law, relative to subrogation to remedies of employees. Referred to the Labor Committee.

This amendment makes provision for an award where a third party is involved and defines how the medical services that may have been provided by the employer shall be deducted by the third person or corporation from the sum paid in release or judgment to the injured employee or his dependents.

Assembly Int. Number 742—Coughlin, amends the Workmen's Compensation Law by adding to list of occupational diseases for

which compensation is payable, all disabling diseases and disabling illnesses. Referred to the Labor Committee.

Another blanket occupational disease bill.

Assembly Int. Numbre 761—Schanzer, amends the Public Welfare Law by providing occupancy and ownership of a single family dwelling by a person shall not in itself make him ineligible for relief and care at expense of public welfare district or the state. Referred to the Ways and Means Committee.

ACTION ON BILLS

Senate Int. Number 155—Berg—practice medicine, person pardoned—has been advanced to third reading in both Houses.

Typewritten copies of the proposed chiropractic bill are circulating.

The osteopathy bill has been introduced in the Assembly by Mr. O'Mara—Assembly Int. Number 715.

Remember the chairmen's conference on Tuesday, February 13th, 10:00 A.M., DeWitt Clinton Hotel, Albany.

Committee on Legislation

Bulletin No. 6, February 16, 1894

Since the issuance of our last bulletin the following bills have been introduced:

Senate Int. No. 630—Byrne; Assembly Int. No. 826—Condon, Labor Law, establishing an unemployment reserve fund to which employers must contribute sum equal to 3 per cent of payroll of employees qualified to receive benefits, agreement as to contributions by employees being void; and appropriating \$40,000. Referred to the Finance Committee.

Senate Int. No. 640—Crawford, Agriculture and Market Law, defining preserves, jellies and apple butter and providing that addition of pectinous material in preparation of fruit jams, preserves or jellies shall not be deemed an adulteration of food. Referred to the Agricultural Committee.

Senate Int. No. 690—Esquirol, amends the Education Law by providing that an applicant for examination for registered nurse must be citizen of the United States, except that this provision shall not apply to nurses who give their services free of charge to a charitable or religious agency. Referred to the Education Committee.

Senate Int. No. 730—Fearon; Assembly Int. No. 1011—Wadsworth, Tax Law, imposing a 2 per cent tax on gross receipts of all business and service transactions with certain exceptions, 90 per cent of revenue to go to cities, towns, villages and school districts outside cities and appropriating \$5,000 for Tax Department and \$25,000 for Audit and Control Department. Referred to the Finance Committee.

This is the long-expected 2 per cent sales tax. Physicians are not exempted as they were last year.

Assembly Int. No. 806—Neustein, Executive Law, to permit without censorship or payment of fees, exhibition of "current event," scientific and educational films and making other

provisions relative to motion picture censorship. Referred to the Ways and Means Committee.

This is the second time this bill has been introduced. Our interest in it is that it would permit the use of educational films without censorship or payment of fees.

Assembly Int. No. 814—Neustein, amends the New York City Inferior Criminal Courts Act, by enlarging jurisdiction of special sessions courts held by city magistrates to include violation of Art. 22, Public Health Law, where defendant is charged with possessing narcotics and pleads guilty. Referred to the Codes Committee.

Assembly Int. No. 901—Rapp, adds new section to Indian Law, requiring State Social Welfare Department to employ competent physician at \$1500 a year to give medical care to Indians on Tonawanda reservation. Referred to the Ways and Means Committee.

Assembly Int. No. 969—Bartholomew, Workmen's Compensation Law, giving claimant right to bring claim before any court having jurisdiction, provides appliances shall not reduce compensation; for payment of award within 10 days of date of receipt of notice, payments not to cease without order, carrier's physician not to be present at examination, all referees to be lawyers with 10 years' experience and making other changes. Referred to the Labor Committee.

The section of this amendment which is particularly interesting to physicians is that which provides that the carrier's physician shall not be present when the patient is examined by the Department of Labor's expert. This bill, however, does not exclude the family physician from the examination.

HEARINGS

Feb. 27—2 P. M.—Joint hearing on all labor bills.

Feb. 28—2 P. M.—Antivivisection bill—Assembly Int. No. 364—Breen.

Mar. 6—2 P. M.—Pharmacy, practice of—Assembly Int. No. 415—Dunkel, drugs, barbituric acid, etc.—As. Int. No. 417—Dunkel.

On Thursday, February 15, the Regents accorded the chiropractors an opportunity to explain the bill they propose introducing this year. Their spokesman was Julius Henry Cohen, at one time attorney to the Port Commission of New York City. The Regents also invited the Medical Society to make such comments as it might.

Flaherty asked Dr. Varen, a member of the State Board of Medical Examiners, and Dr. Aranow, Chairman of the Legislative Committee, to make such objection as the Society would like to have made to the proposed bill. The principal objection was leveled at that section which would oblige the Regents to appoint a special examining board to be composed entirely of chiropractors, admitting of neither physicians nor osteopaths. Representatives of the Medical Society employed is as possibly be; and are willing that shall be exam-

ined in practically the same subjects as are the medical men examined in at the present time, there is no necessity for a special board. The chiropractors made a point of having their candidates examined in the principles of chiropractic, but since the State Board makes no examination in *materia medica* or the principles of osteopathy, there would be no necessity of examining in the principles of chiropractic. We urged the Regents not to be persuaded to lower our present high educational standards. Mr. Cohen, in closing his remarks, stated very emphatically that the chiropractors would not submit to an examining board which included medical men. The Regents have not as yet announced any opinion or decision upon what they heard.

Just a word about the conference of county chairmen which was held in Albany on Tuesday. Twenty-five counties were represented and we had a very interesting and profitable conference. We reviewed all the bills in which we have an interest and discussed their merits and demerits. We are sorry that every county could not be represented, but we appreciate the difficulty of arranging a time that would suit all. If those chairmen who were not present would like additional information as to what transpired at the time, we shall be glad to answer any questions they may have to ask.

The particular bill for you to concentrate upon at the present time are:

APPROVED

Senate Int. No. 66; Assembly Int. No. 296: Hospital lien bill, including physicians.
Assembly Int. No. 289: Free choice of physician.

DISAPPROVED

Senate Int. No. 45; Assembly Int. No. 141, No. 169, No. 570, No. 728: Occupational disease bills.
Senate Int. No. 235; Assembly Int. No. 419: Labor clinics.
Senate Int. No. 336: Antivaccination bill.
Senate Int. No. 450; Assembly Int. No. 715: Osteopathy bill.
Senate Int. No. 505: Physiotherapy bill.
Assembly Int. No. 364: Antivivisection bill.

Conference of Chairmen of County Society Committees on Legislation

Twenty-five County Society Legislative Committees were represented at a conference held by the State Committee in Albany on Tuesday, February 13. About half a dozen others wired or wrote their regrets at not being able to attend.

At the opening of the meeting Dr. Lawrence briefly explained the rather intricate relationship of the various relief organizations now operating throughout the state (see below).

Following this, a very thorough review was made of the bills now before the Legislature which have a medical aspect. Each bill was read and its intent discussed, after which approval or disapproval was recorded for the instruction of the State Committee. Several methods of procedure for securing effective action from the legislators were discussed.

It was decided that each chairman should have members of his own committee communicate with his legislators and members on the important committees, not only opposition or approval of bills, but accompany each with a brief explanatory statement.

Some of the bills toward which concerted action was definitely planned are the following: For *approval*, that hospital lien bill in which physicians and nurses are recognized; for *disapproval*, the bills on antivivisection, antivaccination, physiotherapy, osteopathy, creation of a state insurance fund, creation of rehabilitation clinics by the Department of Labor, investigation of the Workmen's Compensation Law, and 2 per cent sales tax.

There were also present at the conference, Dr. Bedell, President-elect; Dr. Irving, Secretary of the Journal Management Committee; Dr. Morton, Chairman of the Committee on Medical Research; Dr. James N. Vander Veer, Past-President. Dr. Fisher, Past-President, was present as chairman of the Oneida County Society Legislative Committee. A telegram was read from Secretary Dougherty expressing his regrets at not being able to be present.

CHANNELS FOR RELIEF

Under the new Welfare Law, welfare commissioners are obliged to provide medical attention for the indigent, as well as food, clothing, and shelter. The law requires that the welfare commissioner appoint a physician or physicians to furnish medical care either in the home or in a hospital, but physicians are expected to receive written authorization from the commissioner before making more than one visit. Hospitalization must be authorized by the county commissioner. Fees are to be in proportion to the regular fees ordinarily charged by physicians for work in that economic class. But the welfare commissioner may not be able to pay such fees with the budget at his disposal. Therefore, the physicians should, through conference with the commissioner, arrange for satisfactory compensation.

The Temporary Emergency Relief Administration (TERA), from the funds made available through the sixty-million-dollar bond issue, assists the welfare commissioners by refunding to them 40 per cent of the amount expended on home and work relief. Naturally, this refund applies to funds expended in providing medical care *in the home*. It does not apply to hospitalization charges or to salaries paid physicians where home relief is provided in that way. Thus, there is no refund made to municipalities employing physicians on contract with definite salary.

In December the Federal Government undertook to assist the states in providing work for the indigent by creating the Civil Works Administration (CWA) to administer a portion of the funds appropriated to the Federal Public Works Administration. The CWA offered to take over from the welfare commissioners and the TERA all persons employed on work relief and pay them from Federal funds. The state accepted the offer and the TERA instructed the welfare commissioners that they could divert to home relief the money that they

had been devoting to work relief and the TERA would in the future refund them, instead of 40 per cent, 66 $\frac{2}{3}$ per cent of the amount expended. Persons employed on work relief were insured by the municipalities employing them, the insurance being carried either by the State Fund or commercial companies. When they were transferred to the CWA and paid by Federal funds, the insurance was assumed by the United States Employees' Compensation Commission, which promptly sent instructions to all directors of CWA works to provide medical care for the injured by conferring with the local medical organization and having a list of physicians qualified and willing to do this work made available so that the director could select from the list when physicians or surgeons were needed, and provision was made that the injured person might make a choice of physician if he desired.

Physicians working under the CWA are furnished report sheets upon which they are expected to make frequent reports of the services they render, and compensation is provided at the rates ordinarily charged for persons in that economic class.

Another group, working under the Civil Works Service (CWS), are provided medical care by the state, the insurance being carried by the State Fund. Our information is that the State Fund does not admit of free choice of physician by the employee, but has advised the directors of certain designated physicians to be employed if medical service is required.

There is another form of medical service available under the CWA. A community may have a medical project, as for instance, supplementing the dispensary service at a stipulated salary. An example of this is found at the Buffalo City Hospital where twenty-six physicians were employed for two hours a day for six days in the week at \$1.75 per hour, to assist with the dispensary work.

Dr. Lawrence urged the chairmen to do what they can to arouse interest among the physicians of their several County Societies in the administration of these methods of relief and especially to do what they can to encourage the widespread use of the methods which permit patient selection of his own physician

JOSEPH S. LAWRENCE,
Executive Officer

COMMITTEE ON PUBLIC RELATIONS

The Chairman addressed the following letter to the County Societies under the date of February 12, 1934.

Dear Doctor:

When physicians collect fees for services performed in these days they may collect from (1) the patient himself, or they may collect from (2) an insurance company if the patient is employed in industry, or from (3) the State Fund if he happens to be employed on the state highways, the CWS, or in industries carried by the State Fund, or (4) by the United States Employees' Compensation Commission if he is employed under the CWA, or (5) from the welfare commissioner if he is unemployed and an indigent.

Naturally, the question of fees becomes a very important factor when there are so many

employers and not a little influence is exerted by the fact that until recently the physician was donating medical care to some of these people. Some County Societies have endeavored to create and employ a schedule of fees, but have found it very difficult to devise a schedule that could be used satisfactorily at all times.

The Committee on Temporary Emergency Relief has had numerous conferences with state officials administering the TERA funds, the Committee on Medical Economics has given the general subject of fee schedules a great amount of profound study and has assisted a number of County Societies in adjusting their difficulties, and the Standing Committee on Public Relations has approached the problem from the point of view of establishing satisfactory cooperating relationships between the governing bodies of the various official agencies administering the several relief funds and the leaders of the County Societies.

On the subject of fee schedules, the Public Relations Committee adopted a resolution which was presented to and adopted by the Executive Committee of the State Society and which is now offered to you for the consideration of your County Society. It follows

COMPENSATION OF PHYSICIANS FOR SERVICES RENDERED INDIGENTS

"Physicians are not concerned with the care of indigents for the purpose of gain but to render needed service in the prevention and treatment of disease. Compensation sufficient to protect physicians against economic loss is rightfully expected and should be provided from public funds.

The Public Relations Committee doubts the wisdom of adopting a fee schedule—in itself—as a guide for compensating physicians for the care of indigents. The committee is of the opinion that a committee in each County Society should establish close cooperative relationship with government representatives. In conference they should decide the compensation to be paid physicians.

It is to be especially stressed that compensation for the care of indigents will be minimum and not representative of charges made by physicians for like services rendered patients supporting themselves from personal funds.

Cooperation between government welfare officials and duly elected representatives, preferably the Public Relations Committee, of the County Medical Society, should result in a satisfactory agreement."

JAMES E. SADLEIR, *Chairman,*
Committee on Public Relations

PRIZE ESSAY ANNOUNCED

The Medical Society of the State of New York takes pleasure in calling to the attention of the medical profession of the State the following prizes which are offered annually and the winners announced at the Annual Meeting of the House of Delegates.

The *Merritt H. Cash* prize will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who are residents of New York State.

The essay shall be typewritten or printed, and the only means of identification of the author shall be a motto or other device. It shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer.

The *Lucien Howe prize* will be presented for the best original contribution to our knowledge of surgery, preferably ophthalmology, and is not limited to members of the Medical Society of the State of New York.

The method of presenting the communication and of awarding the prize shall be substantially the same as that followed in regard to all prize essays. That is, the communica-

tion shall be typewritten or printed, and the only means of identification of the author shall be a motto or other device. It shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer. If, in any year, the committee does not deem any essay or communication which is offered worthy of the prize, then it shall not be awarded.

Essays should be sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 2 East 103rd Street, New York City, not later than April 15, 1934, in order to be judged before the Annual Meeting on May 14, 1934.

'BRAIN SIZE AND MENTAL ABILITY

The question whether the size of the brain denotes mental ability is agitating British psychologists as a result of measurements that have been made of the brains of African natives in the Kenya Colony (British). As reported by the London correspondent of the *Journal of the A. M. A.*, Dr. H. L. Gordon, visiting physician to the Mathari Mental Hospital, Nairobi, Kenya Colony, determined the cranial capacity of 3,444 unselected natives, representing the average of the Kenya population. The average cubic capacity was 1,316 c.c., against the European 1,481. He also found that from the ages 10 to 20 years the average yearly growth of the native brain was 8.5 c.c., against the European 17.7. Further, after puberty the curve of growth of the European brain rises steeply but that of the native scarcely at all. The measurements and statistical data were submitted to Mr. Walter, statistician to the conference of East African governors. Dr. Gordon carried his observations into the laboratory with the expert help of Dr. F. W. Vint, pathologist to the Kenya government. He found that the brains of 100 normal males averaged 150 gm. less than Europeans. Dr. Vint's results (to be published in the *Journal of Anatomy*) showed that the cortex of the native brain was 15 per cent less than of the European and that its cells were smaller, less well formed and less well arranged than those of the European. Further, although there was no reduction in the number of cells in any given area, the native cortex showed predominance of undifferentiated cells. Finally, Dr. Gordon found that, while dementia praecox is unknown among natives living their own life, every native in which it occurred had received some European education. In view of the rapid introduction of European civilization into Africa, these observations are important. Dr. Gordon holds that "the hand of science, with all its power, has not yet been held out to enable the native to rise."

Dr. Cyril Burt, professor of psychology at University College, London, disagrees with the conclusion that efforts to educate the natives may induce insanity, because it is contrary to current theories and current practice. The notion that mental ability can be gaged by measuring the skull has been abandoned. The

correlation between skull capacity and inborn intelligence is certainly positive but far too small to be of diagnostic value. The skull capacity varies far more closely with physical characteristics—height, weight, age, sex, race—than with mental characteristics. The greater part of the brain is concerned with physical and not intellectual activities. Dr. Vint's observations on the cells of the cortex are more suggestive, but he is far more cautious in drawing psychologic inferences than Dr. Gordon and says that "the functions of the human brain are still wrapped in mystery." It is commonplace among psychologists to-day that mental characteristics should be judged by mental symptoms, not by physical. Professor Burt quotes from Dr. Oliver, who has recently described in the *East African Medical Journal* tests performed in two large schools in Kenya, one native and the other European. He found that the average native intelligence was only about 85 per cent of the European; nevertheless, 14 per cent of the natives actually surpassed the European average. Moreover, the fathers of the European children were largely government official and professional men, which should give a somewhat high European standard.

Prof. Julian Huxley points out that brain weights of individuals or types are to be compared only in terms of relative brain size. Lapique showed that for different types of mammals or for the sexes the brain varies as the body weight raised to the power 0.56. When men and women are so compared their "coefficient of brains" or relative brain size is identical, though woman's brain is distinctly the smaller. The average size of the natives measured by Dr. Gordon appears to have been much less than that of Europeans, which to some extent would account for smaller brains. Professor Huxley thinks that the abler natives are perfectly capable of profiting by the best education that can be given them. Prof. J. B. S. Haldane satirizes Dr. Gordon's conclusion. He points out that Martin found that the average capacity of the Eskimo brain is 1,563 c.c. and thus exceeds the European. If the Kenya natives are to be protected from European education, Europe should also be protected against the disintegrating effects of Eskimo culture!

County News

New York

Maternal Mortality.—A joint meeting under the auspices of The New York Academy of Medicine, New York Obstetrical Society, and The Medical Society of the County of New York will be held Wednesday, March 7, 1934, at 8:30 p. m. at The New York Academy of Medicine on the Constructive Aspects of the Academy of Medicine Report on Maternal Mortality.

A resumé of the report will be given by Dr. Harry Aranow. Conclusions and recommendations of the report by Dr. George L. Brodhead. Significance of the report and the measures suggested for carrying out its recommendations by Dr. George W. Kosmak.

Discussion by Dr. A. W. Bingham, East Orange, New Jersey, Dr. Clifford B. Lull, Philadelphia, Dr. Edward C. Podvin, New York City, Dr. S. S. Goldwater, Commissioner of Hospitals, Dr. John L. Rice, Commissioner of Health, and Dr. Thomas L. Parran, State Commissioner of Health.

Onondaga

The Comitia Minora of the Onondaga Medical Society has recently directed its Medical Economics Committee to make a survey of the gratuitous work done in Onondaga County by the medical profession during the year 1933, and has further instructed the Committee to ascertain, if possible, the monetary value of these services.

Discussion on Economics.—The Society deviated from its usual custom at the February meeting, having voted to dispense with the scientific program and to devote the entire evening to the discussion of matters bearing on the present economic situation as they pertain to medical practice.

Dr. Leo E. Gibson, Chairman of a special committee, proposed the use of statistical reports in the study of medical problems in Onondaga County.

Additional reports were received from the Legislative and Public Relations Committees, which latter body has been making a study of the problems of medical fees as they pertain to compensation and welfare cases.

Dr. Joseph S. Lawrence, Executive Officer of the State Society, who had been invited to address the members, was called upon to explain some of the technicalities arising in connection with the TERA and the CWA as they affect the physician.

At the close of the discussion, Dr. Thomas P. Farmer introduced the following resolution which was adopted by the Society:

"RESOLVED, that it is the sentiment of the Onondaga Medical Society that physicians should be compensated for medical services rendered to indigents;

"AND THAT such compensation be adjusted on the same basis as compensation paid for other services and supplies for indigents;

"AND THAT the Public Relations Committee be instructed to proceed to confer with the appropriate county, city and town officials for the purpose of putting the above mentioned principles in effect.

"AND THAT the Public Relations Committee be given full power to act for the Society in so doing."

That the majority of the members are vitally concerned with the present-day medical problems was evidenced by the large attendance at this session, and by the fact that the discussion lasted until after 11:30 P. M.

Postgraduate Courses.—Through the cooperation of the Public Health and Medical Education Committee of the Medical Society of the State of New York, the local Postgraduate Committee has been conducting a course of lectures on Dermatology and Syphilology.

These lectures, which are being held each Thursday evening in the auditorium of St. Joseph Hospital, have been exceptionally well attended, and the speakers up to date have been: Drs. Sulzberger, Niles, Lewis, Stone, and Abramowitz, all of whom are associated with the Department of Dermatology and Syphilology of the New York Postgraduate Medical School, Columbia University.

The remaining three lectures will be given by Drs. Cipollaro, Wise, and Rosen.

Officers.—Dr. Thomas P. Farmer, President of the Society in 1933, was succeeded by Dr. Charles D. Post on January 1, 1934. Dr. Thomas F. Laurie was elected to the Vice-Presidency, and the Secretary and Treasurer were reelected to their respective offices.

OUR MENTAL TELEGRAPH SYSTEM

Electrical instruments so delicate that they will register a millionth of a volt are being used to explore microscopic areas of the brain, Prof. C. Judson Herrick of the University of Chicago told the American Association for the Advancement of Science, as the Diplomat reports him. Information thus obtained is expected to revolutionize our whole knowledge of the way the human mechanism works.

"I venture the prediction that the electro-biological era now beginning will yield as revolutionary changes in our conceptions of the physiology of the nervous systems as the invention of the microscope inaugurated in an-

atomy," Professor Herrick told his audience.

There are from ten to fourteen billion nerve cells in the cerebral cortex, arranged in definite patterns. It is the little electric currents that flow from cell to cell and from group to group that the new electrical methods are measuring. This new knowledge of intercell telegraphy in the brain promises to yield positive results in understanding differences in behavior between man and his evolutionary cousins, the higher apes, and among the human race themselves, that the older methods which, dependent on study of the grosser brain features, could only block out roughly.

Medicolegal

Counsel, Medical Society of the State of New York

CONSENT TO OPERATION—AN INTERESTING CASE

"Every human being of adult years and sound mind has a right to determine what shall be done with his own body; and a surgeon who performs an operation without his patient's consent, commits an assault, for which he is liable in damages. This is true except in cases of emergency where the patient is unconscious and where it is necessary to operate before consent can be obtained."

These words are taken from an opinion written by the former Chief Judge Cardozo of the Court of Appeals of this State.

When an emergency, in fact, exists so as to permit a surgeon either to operate or to extend the field of the original operation, where the consent of the patient has not been first obtained, is not always an easy question to answer.

A few months ago a high court of one of the Canadian provinces handed down an extremely interesting decision upon the point. A detailed statement of the facts is necessary to a proper understanding of the ruling of the Court.

The plaintiff was a man about fifty years of age whose vocation was that of master mariner. At about the age of twenty, he had fallen and fractured his spine and injured certain nerve trunks. He sustained a permanent loss of sensation on the back of his legs and around the buttocks, and some paralysis of the muscles of his feet. He first consulted the defendant doctor in 1921, and upon being examined told of his injuries previously received. At the time, he had very poor control over his kidneys and bowels and was wearing a rubber urinal. The doctor treated the bladder condition and performed a circumcision upon the man. Later in the same year he was treated for a fistula.

In 1929, the man again consulted the defendant. He was then suffering from fever, headache, dry tongue, sinus infection and general septic poisoning. His urine indicated an infection, and a diagnosis of bladder and kidney stones was made. An operation for the removal of the stones was performed. His bladder condition improved, and he developed a severe pain in the left groin. He was next operated on for an abscess about the kidney. The doctor attributed the pain in the groin to a hernia condition and advised another operation with respect to it. The patient in discussing his symptoms with the doctor, told him that he wanted the hernia cured, and was told that there was a reasonable chance of success in curing it. No other operation was discussed at the time than one for the ordinary treatment of hernia. The operation so discussed was consented to.

The doctor had the man put under a general anesthesia, and made the usual incision. Upon

opening the inguinal canal, the left testicle appeared and was found grossly diseased, being enlarged, nodular and softened. In the surgeon's opinion, in order to bring about a satisfactory cure for the hernia, it was necessary to remove the testicle. He also believed that its removal was indicated because, if left, it would be a menace to the health and life of the patient. Using his best judgment, therefore, under the circumstances, the doctor removed the testicle. Examination of the testicle after the operation revealed multiple abscesses indicating, in the doctor's opinion, that it might have become gangrenous, causing a serious condition of blood poisoning. The man remained in the hospital for some time and eventually his general health improved.

Thereafter the patient brought an action against the doctor making the following charges:

"1. That after being employed to perform and while performing an operation on the plaintiff for the cure of a hernia, and while plaintiff was under the influence of an anesthetic, the defendant without the knowledge or consent of the plaintiff removed the plaintiff's left testicle;

"2. In the alternative, that the defendant was negligent in diagnosing the case and in not informing the plaintiff that it might be necessary in treating the hernia to remove the testicle; and

"3. In the further alternative, that in removing the testicle in the above-mentioned circumstances, the defendant committed an assault upon the plaintiff."

The case came on for trial and there was no serious conflict as to the facts except as to the question of the plaintiff's condition after the operation. The professional skill of the surgeon was not challenged, and there was no question but that the operation was skillfully performed. Several doctors called by the defendant corroborated him in his contentions that what he did was "good surgery," that the condition found could not be anticipated before the operation, and that if the testicle had not been removed, the life and health of the patient would have been endangered. The court concluded from all the evidence that the following propositions were clearly established:

1. That there was no express consent to the removal of the testicle;

2. That no consent thereto could be implied from conversations between the parties

before the operation, and that neither had contemplated the situation which arose;

3. That the removal was necessary for the health of the patient, and that the defendant in good faith upon the operation believed it was reasonably indicated to preserve his life.

The court in deciding the case, reviewed the authorities in England, Canada, and the United States, and came to the conclusion that the plaintiff's action should be dismissed. In its opinion the court summarized certain principles which it felt had been established as follows:

"1. That in the ordinary case where there is opportunity to obtain the consent of the patient, it must be had. A person's body must be held inviolate and immune from invasion by the surgeon's knife if that operation is not consented to. The rule applies not only to an operation but also to the case of mere examination, and it is pointed out in Taylor's Medical Jurisprudence, page 59, that although the fact that a visit paid by a private patient to a practitioner implies consent to a certain amount of examination, it must not be concluded that such a visit entitles the practitioner to compel examination more intimate than the patient desires. Such an examination can only be made with the patient's consent; if made without such consent, it is technically an assault.

"2. That such consent by the patient may be expressed or implied. If an operation is forbidden by the patient, consent is not to be implied and Taylor again says: 'It must be constantly remembered that in this connection silence does not give consent, nor is compliance to be taken as consent.'

"3. That consent may be implied from the conversation preceding an operation or from the antecedent circumstances. It is said that if a soldier goes into battle with a knowledge beforehand that surgeons attached to the army are charged with the care of the wounded, the consent of the patient may be implied therefrom for such operations as the surgeon performs in good faith on a soldier."

The court pointed out that irrespective of a precedent squarely in point, its ruling would be in favor of the physician, and said:

"In the case at bar, I find that the defendant after making the incisions on plaintiff's body, discovered conditions which neither party had anticipated, and which the defendant could not reasonably have foreseen, and that in removing the testicle he acted in the interest of his patient, and for the protection of his health and possibly his life. The removal I find was in that sense

necessary, and it would be unreasonable to postpone the removal to a later date. I come to this conclusion despite the absence of expressed or possibly of implied assent on the part of the plaintiff."

One of the cases commented upon in the ruling was an earlier case decided in one of our midwestern States. In that case the facts were held to justify a different decision. There an operation upon the right ear had been consented to. When the patient was under the anesthetic, the left ear was examined and found to be in a more serious condition than the right ear, and it was operated upon.

In that case the plaintiff recovered judgment, the court finding from the proof that the condition of the ear operated upon was not of so serious a nature as to prevent reasonable opportunity of obtaining the consent of the patient before undertaking to operate upon the left ear. In that case the court said, however:

"Reasonable latitude must, however, be allowed the physician in a particular case; and we would not lay down any rule which would unreasonably interfere with the exercise of his discretion, or prevent him from taking such measures as his judgment dictated for the welfare of the patient in a case of emergency. If a person should be injured to the extent of rendering him unconscious, and his injuries were of such a nature as to require prompt surgical attention, a physician called to attend him would be justified in applying such medical or surgical treatment as might reasonably be necessary for the preservation of his life or limb, and consent on the part of the injured person would be implied. And again, if in the course of an operation to which the patient consented, the physician should discover conditions not anticipated before the operation was commenced, and which, if not removed, would endanger the life or health of the patient, he would though no express consent was obtained or given, be justified in extending the operation to remove and overcome them."

In another decision rendered some years ago, another similar dictum was pronounced as follows:

"Where the patient desires or consents that an operation be performed and unexpected conditions develop or are discovered in the course of the operation, it is the duty of the surgeon, in dealing with these conditions, to act on his own discretion, making the highest use of his skill and ability to meet the exigencies which confront him, and in the na-

ture of things he must frequently do this without consultation or conference with anyone; except perhaps other members of his profession who are assisting him. Emergencies arise, and when a surgeon is called it is sometimes found that some action must be taken immediately for the preservation of the life or health of the patient where it is impracticable to obtain the consent of the ailing or injured one or any one authorized to speak for him. In such event the surgeon may lawfully, and it is his duty to perform such operation as good surgery demands, without such consent."

Erysipelas Alleged to Have Resulted from Doctor's Negligence

A doctor, specializing in gynecology, was consulted by a young colored woman, who made numerous complaints about her condition, including nose bleeds, cold, pains in abdomen, and constipation.

He examined her and found tenderness on pressure at the iliac fossa; her cervix was inflamed, and she had an acute rhinitis with coryza. He prescribed a syrup cough medicine, directed her to take a laxative, and use a douche vaginally. She came back about six weeks later to see the doctor. At that time her cold was better and she made no complaints of nose bleed. The doctor again examined her cervix and found the inflammation had cleared up, and she was not complaining of abdominal pains. Using a speculum and applicator he applied a cautery to her cervix. She returned about a week later and he found her condition of the cervix almost normal and decided to give her a few injections of sodium iodide. She consented to this and he administered an injection of 20 c.c. intravenously. A similar injection was given to her a week later.

When she returned for further treatment about two weeks thereafter, she had developed a condition of erysipelas of the thigh, which the doctor treated with exposure to his Alpine lamp and prescribed ichthyol salve and heat applications. The patient thereafter did not return to the doctor.

She later brought suit against the doctor, charging that in treating her he had been negligent in that he had administered hypodermics in an excessive amount and in injurious doses, which, according to the plaintiff's complaint, were alleged to have caused the condition of erysipelas that developed.

The case was reached for trial in its regular order and plaintiff's attorney made re-

peated attempts to obtain a settlement on behalf of his client, which, of course, the defendant refused to consider. On the eve of trial the plaintiff's attorney realizing the weakness of his claim against the doctor voluntarily agreed to discontinue the action.

Alleged Negligence in Appendectomy

A doctor, specializing in surgery, was called by a general practitioner to a hospital to perform an appendectomy upon one of his patients. The surgeon agreed and promptly went to said hospital where he found the patient, an eight-year-old girl.

He examined her and diagnosed that she was suffering from acute appendicitis with peritonitis. The history which the surgeon received was that the morning before the patient had developed pain in the epigastrium which radiated to the right lower quadrant and that the patient had vomited several times during the previous twenty-four hours.

He had the patient prepared for operation and promptly performed an appendectomy upon the child. He found a ruptured appendix and closed the abdomen leaving two cigaret drains inserted. The patient's condition improved very well, the surgeon seeing her daily for the next two weeks when her condition was such that she was able to be taken home. At the time she left the hospital the drains had been removed, although there was still a sinus present discharging some pus. He directed that she should be brought to his office from time to time for dressings. He saw her twice thereafter, and each time changed the dressings and the last he heard from the patient was a telephone call informing him that the patient's family physician was taking care of the dressings, as his office was near her home.

It appeared that a few weeks later the doctor attending her discovered that a small abscess about one-half inch below the incised wound had developed. He directed that she should go to the dispensary of the hospital for treatment. A small incision was made and an old suture which had not absorbed was taken out.

An action was thereafter brought against the surgeon charging him with negligence in his treatment of the child in that he had permitted the foreign body to remain in the patient after the operation. After the action had been brought, it was never noticed for trial, and after it had been pending for some years a motion was made on behalf of the defendant to dismiss the case for lack of

prosecution. The day before the said motion was to be argued in court, the attorneys for the plaintiffs voluntarily discontinued the case thereby terminating the matter in favor of the doctor.

Death Claimed Due to Delayed Operation

A general practitioner was called to the home of a family that he had treated from time to time, for the purpose of attending a girl six and one-half years of age.

The child's complaints were a general feeling of sickness and he found on examination that she was suffering from influenza. The doctor prescribed medications and directed her to go to bed. He saw her daily thereafter for five days and on each occasion he examined her carefully (each examination including an examination of the abdomen). He found no evidence of tenderness of the abdomen or other illness. He next received a hurried call to the child's home and found the girl complaining of abdominal pains. He found her abdomen distended and tender and by examination through the rectum discovered a pelvic mass. He suggested a consultation and brought in a surgeon to examine the child. The surgeon suggested that it would be better to delay the operation until it could be ascertained whether the pelvic mass would subside, expressing the opinion that it would be dangerous to operate at that time by rea-

son that the pus might spread through the abscess into the peritoneum, causing peritonitis. When he called upon the patient the following day she was worse and he recommended that she be immediately sent to the hospital and operated upon. The mother objected to the hospital which he suggested and she was sent the same day to another hospital where neither of the doctors who attended the child had connections. It was later ascertained that the child was operated upon the same night by another doctor who found a gangrenous appendix and condition of peritonitis. The child did not rally from the operation and died the following day.

The mother of the child was appointed Administratrix and instituted action against the first two doctors who had attended the child, claiming that they failed to properly diagnose the patient's condition and that as a result she died by reason of the failure of the said doctors to recommend an operation upon the child timely.

The case came before a jury for trial and at the close of the testimony introduced on behalf of the plaintiff, a motion was made to dismiss the complaint on the ground that the plaintiff had failed to establish by competent testimony that the death of the child was caused by any negligence on the part of either of the doctors. The motion was granted and judgment entered in favor of the doctors.

A VINDICATION OF THE LEFT-HANDED

The popular view that left-handed people are inferior in some way, mentally or physically, is hit a hard blow by a German investigator, Professor Bethe, physiologist, of Frankfurt. He notices, it seems, that men who lost their right arms in the World War soon learned to use the left equally well. This seemed to him to disprove the idea that one side of the brain is superior to the other. He found, as reported in the *Journal of the A. M. A.*, that left-handedness is more common than is generally supposed. Among 266,000 soldiers, 10,300, or 3.9 per cent were left-handed. The proportion of left-handed and of right-handed young children is identical, ranging around 17 per cent; the remainder are ambidextrous. With increasing age, the proportion shifts toward the side of right-handedness.

Another series of statistics lists 25 per cent of a group of children as left-handed. Bethe instituted experiments on a large scale on students and reached the conclusion that there is

absolutely no predominance of the right side in the use of the limbs. His investigations showed the proportion of genuine right-handed and left-handed subjects to be as 20 to 25 per cent. The view that left-handed persons are supposed to suffer from physical deformities, mental backwardness, epilepsy, criminal tendencies, strabismus, deafmutism, stuttering, and the like, is discredited by the fact that many distinguished men (for example, Leonardo Vinci and the surgeon Ludwig Rehn) were left-handed. Bethe addressed a questionnaire to four universities, among the members of the faculty of which 20 per cent were left-handed. This is a far greater percentage than is commonly supposed to exist.

Furthermore, the left-handed persons, as a survey showed, were better in the examinations, on the average, than were the other cases. These observations serve to show that there is no evidence for an unequivocal superiority of one hemisphere of the brain over the other.

The Practical Medicine Series. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series, 1933. Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of Obstetrics and Gynecology. Obstetrics, edited by Joseph B. DeLee, M.D. Gynecology, edited by J. P. Greenhill, M.D. 12mo. of 630 pages, illustrated. Cloth, \$2.50.

The Queen Charlotte's Text-Book of Obstetrics. By Aleck W. Bourne, M.B., and others. Third Edition. Octavo of 679 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$5.25.

Maternal Mortality and Morbidity. A Study of Their Problems. By J. M. Munro Kerr, M.D. Octavo of 382 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$8.25.

Combined Text-Book of Obstetrics and Gynecology. For Students and Medical Practitioners. By J. M. Munro Kerr, and others. Second Edition. Octavo of 1100 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$10.00.

A Handbook of Psychiatry. By John H. Ewen. 12mo. of 267 pages. Baltimore, William Wood & Company, 1934. Cloth, \$4.75.

The Nature and Treatment of Amentia. By L. Pierce Clark. Octavo of 306 pages. Baltimore, William Wood & Company, 1933. Cloth, \$4.25.

Fundamentals of Biochemistry in Relation to Human Physiology. By T. R. Parsons. Fourth Edition. 12mo. of 435 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$3.00.

Books Reviewed

NUTRITION SERVICE IN THE FUTURE—Report of the Subcommittee on Nutrition Lucy H. Gillett, Chairman. *Child Health Centers A Survey*. Report of the Subcommittee on Health Centers J. H. Mason Knox, Jr. Chairman. Tillan, L. A. Strauss, Vice Chairman. White House Conference on Child Health and Protection. Octavo of 139 57 pages. New York, The Century Company. Cloth \$2.00.

The first division of this book is a report of a subcommittee of the White House Conference which recommends to the Medical Profession an additional lay helper, namely a nutritionist. From the report the following facts are gathered. The Nutritionist is to be one quarter pedagogue so as to be fortified with the groundwork of effective demonstration, one quarter home economist in order to teach people how to get the most nutritional value for the least money; one-quarter dietitian for the purpose of revealing the secrets of the proper preparation and combination of foods; and finally one-quarter social service worker for the sake of directing the relief of families who are unable to buy sufficient nourishment. Unquestionably the idea is excellent.

There are two sectors to the field, first, the teaching and the supervision of the teaching of nutrition in the schools; and secondly, the application of the art in the Health Center Movement. The committee has in mind only the lay nutritionist and indeed she might well be given the work in the school system. But as regards the Health Center, the supervision should be vested only in a professional helper, that is a physician or a graduate nurse who has specialized in the theory and art of nutrition. The graduate nurse now has the scholastic standing necessary and must take possession of the whole field that is rightly her own but which is being slowly wrested from her by the trained laywomen.

The second division of the book entitled "Health Centers, a Survey" is a statistical summary of the health center movement. The numbers of centers and their distribution are given as well as the numbers and types of assistants and services offered and the numbers, social and racial groups served in the United States and its possessions.

In general the trend of thought of the book is toward Paternalism as might be expected from the composition of each committee. It is to be hoped that the present national movement toward Social Justice will finally convince the country that it is better economic policy to give a fair wage to freemen than to give free gifts to wage slaves and that a resulting self-reliant citizenry will return to the care of the private practitioner by whom his medical needs are best served.

K. G. JENNINGS

Bone Growth in Health and Disease. The Biological Principles Underlying the Clinical Radiological and Histological Diagnosis of Perversion of Growth and Disease in the Skeleton. By H. A. Harris. M.R.C.S. Octavo of 248 pages illustrated. New York: Oxford University Press, 1933. (Oxford Medical Publications.)

The material in this book represents Professor Harris' results of his investigations during the past ten years.

Part I deals with the causes and effects of arrest of bone growth. During any acute disease, there is an arrest of development, such arrests of growth are frequently demonstrated by x-rays taken for other purposes.

Part II deals with bone growth in deficiency diseases, such as rickets and scurvy. There is a splendid description of the sequence of changes occurring at the epiphyseal line. Individual vitamins are specific in certain processes of bone growth, but because there are so many limitations to their bone-forming properties, he sees no further danger of having any vitamin or group of vitamins being accepted as a single panacea for the restoration of disturbances of bone growth.

Part III discusses primary perversions of bone growth as seen in monostrosities, achondroplasia, the effects of syphilis and tuberculosis on bone growth. A chapter on Paget's Disease is timely.

The illustrations are excellent. The text is clear and concise. All those who do bone surgery should read this volume. There are many important facts between its covers.

DONALD E. McKENNA

Die Psychoanalyse und der Praktische Arzt. Vortrag gehalten zu Ehren von Prof. Sigmund Freud 75. Geburtstag in der Deutschen Medizinischen Gesellschaft der Stadt New York am 4. Mai 1931 von Dr. Dorian Feigenbaum. 17mo of 227 pages. (Sonderdruck aus Zentralblatt für Psychotherapie und ihre Grenzgebiete. Band VI. Heft 1.) Leipzig: S. Hirzel [1933].

At the celebration of Freud's 75th birthday, held in May, 1931, Dr. Feigenbaum read this paper before the German Medical Society in New York City. The paper was published in a German medical journal, and is now available in book form. There is very little that may be said, except that one may refer to Dr. Feigenbaum's English publications and get more from them, than from the rather difficult presentation in German.

There are now excellent English presentations of the subject matter, no longer does one need to read German publications to get an idea of psychoanalysis.

IRVING J. SANDS

Obstetrics and Gynecology. Vol. 3. Edited by Arthur H. Curtis, M.D. Octavo of 1701 pages illustrated and General Index. Volumes 1, 2 and 3. Octavo of 137 pages. Philadelphia: W. B. Saunders Company, 1933. Cloth. Complete set, including index \$35.00.

The authors of the various chapters in volume 3 of this series are well known. The book is a valuable addition to the pelvic vic organs, disturbances of function, and considerable space is devoted to the endocrines in

gynecology and obstetrics. Special diseases and important symptom complexes are discussed in detail, and the latter half of the book is devoted to special problems in relation to gynecology, such as the colon and the appendix, the urinary tract, roentgenography, radiotherapy, blood transfusion, etc.

These volumes must be read to be appreciated. The reviewer knows of no other work which is so comprehensive, and so well edited as this.

Obstetrics and Gynecology should be read by all those who are interested in the practice of this specialty.

The general index for all three volumes is in a separate book of 137 pages.

WM. SIDNEY SMITH.

Pathogenic Micro-organisms. A Practical Manual for Students, Physicians and Health Officers. By William Hallock Park, M.D., and Anna Wessels Williams, M.D. Tenth Edition. Octavo of 867 pp., illustrated. Philadelphia, Lea & Febiger [c. 1933]. Cloth, \$7.00.

This classical work, arranged in three parts, is a practical manual for students, physicians, and health officers. Part I deals with the general characteristics and methods of study of micro-organisms. Part II discusses the study of the individual disease producing micro-organisms. Part III presents certain practical aspects of the subject, such as the bacteriological examination of water, air, and soil, and sewage disposal, bacteriology of milk, shellfish, and practical sterilization. This new edition includes many changes. The practical application of immunization against diphtheria and scarlet fever is given, as well as other problems of immunity. It also includes the recent additions to our knowledge of yellow fever, poliomyelitis, bacteriophage, undulant fever, and others. There are many other revisions and additions which bring this treatise on micro-organisms to date.

EDWARD H. NIDISH.

Bacteriology for Medical Students and Practitioners. By A. D. Gardner. 16mo. of 276 pages. New York, Oxford University Press, 1933. Cloth, \$2.25.

In his preface, the author states that the chief aim of his book is to present shortly, readably, and relevantly, as much of bacteriology as a medical student or practitioner needs to know, but in this the reviewer does not believe that he has entirely succeeded. While he has made his subject very readable, indeed, its very conciseness militates against any real usefulness, so that it is at best, only a very good outline of bacteriology.

ISADOR COHN.

If I Have Children. By G. Francis Smith, M.R.C.S. 12mo. of 133 pages. New York, Oxford University Press, 1933. Cloth, \$1.75.

Dr. Smith has given a short, and yet a sufficiently detailed summary of hygiene as applied to the problem of the expectant and inexperienced or troubled mother. His advice is sound in all respects and his explanations of the beginnings of behavior problems and their treatment will soothe the worries of many a mother. While religion is the most important feature of the lives of all of us, whether we admit it or not, in a book like this

it would have been better to have dismissed it as such rather than to have given personal views on the subject. With this single objection the book is an excellent handbook for mother, guardian, teacher, nurse, and nurse-maid.

KENNETH G. JENNINGS.

The Practical Medicine Series. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Series 1933. Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of General Medicine, edited by George F. Dick, M.D., and others. 12mo. of 831 pages, illustrated. Cloth, \$3.00.

The scope of this book is the same as in past years consisting of quite full abstracts from the principal articles of the leading American and foreign journals. The department editors are Dick, Lawrason, Brown, Minot, Castle, Stroud, and Eusterman. In the section on Infectious Diseases, scarlet fever toxin and antitoxin are considered to be more valuable than formerly, and work on the etiology of arthritis emphasizes the frequency of the hemolytic group of streptococci rather than the *viridans*. All branches in the field of internal medicine are thoroughly covered.

The book furnishes an economical and easy way of keeping up with the progress made and is well worth a yearly subscription.

W. E. MCCOLLOM.

A Study of Rural Public Health Service. For the Committee on Administrative Practice of the American Public Health Association by the Sub-Committee on Rural Health Work. Edited by Allen W. Freeman, M.D. Octavo of 236 pages. New York, The Commonwealth Fund, 1933. Cloth, \$2.50.

This book gives a very good cross section of rural public health work in the United States. It is a good reference work for health workers. It shows the need for the keeping of accurate records and also the woeful lack of coordination in the administration of health activities in the United States. The contrast between the work in the organized and unorganized area is quite marked, the advantage being greatly in favor of organization.

Dr. Freeman is to be commended for the painstaking care in the compilation of a great mass of statistics and for the impartiality with which he has made his comparisons.

A. D. JACQUES.

The Practice of Podiatry.—By Reuben H. Gross, M.C.P. and E. K. Burnett. Edited by Maurice J. Levi, M.D. Octavo of 451 pages, illustrated. New York, Harriman Printing Company, 1933.

Although this book is intended primarily for the podiatrist, it contains information which will render it of great value to the medical practitioner as well, and particularly to the orthopedic surgeon. The description of footwear is most interesting and instructive. A great variety of subjects is covered, but throughout the text the authors clearly designate where the province of the podiatrist ends and that of the physician begins. The information compiled in this book is presented in a most concise manner, with diagnosis and treatment of the various conditions clearly considered. The book is complete in its detail, well printed and illustrated, and can be fully recommended.

JEROME WEISS.

THE RELATION OF BILIARY DYSFUNCTION TO LITHIASIS

LESTER R. WHITAKER, M.D., F.A.C.S.

From the Evans Memorial for Clinical Research and Preventive Medicine, Boston University School of Medicine, and the Surgical Clinic of the Massachusetts Memorial Hospitals

Since stones are formed chiefly from constituents of the bile, an inquiry into conditions favoring precipitation or crystallization in this medium is essential to a study of the mechanism of cholelithiasis.

Cholesterol is the most important substance concerned with gallstone formation; it is probably involved at the very beginning of the vast majority of gallstones. Cholesterol is insoluble in water; yet the bile is an aqueous medium containing cholesterol and other substances. This must be affected by special chemical relations in the bile. All agree that cholesterol is held in colloidal dispersion by the action of bile salts. Cholesterol is even more freely dispersed in the lipids of the bile which have been emulsified by alkali cholates—the bile salts.¹ There is probably a fairly definite ratio of bile salts to cholesterol and lipids, which is essential to prevent crystallization. Anything which disturbs this ratio provides the first step in stone formation. This may arise:

1. Through changes in the blood from which bile is manufactured.
2. From dysfunction in the liver itself whereby it secretes an altered bile.
3. From abnormal anatomical or functional states in the extrahepatic biliary passages.

Let us examine some of these factors:

HYPERCHOLESTEROLEMIA is the most significant aberration of the blood in cholelithiasis, a relation between the two conditions having been observed often in patients.² The blood cholesterol is elevated in pregnancy.^{3,4} With many a woman the onset of symptoms follows the birth of the first child. Diabetics, in

whom the incidence of gallstones is increased, also show hypercholesterolemia.⁵ In experimental animals overfeeding with lipids,⁶ or intraperitoneal injections of cholesterol emulsion,⁷ can produce an increase of cholesterol in the blood, and masses similar to gallstones in the bile. It is interesting to note that high feeding of butter-oil to lactating goats produces marked increase of combined cholesterol and of total lipids in the blood plasma.⁸ This gives us a hint for prophylaxis in pregnant and lactating women.*

DISTURBANCE OF THE LIVER leading to secretion of abnormal bile may presumably arise from four sources:

1. Infections: hematogenous, from a systemic or portal focus; ascending, through the bile ducts; or by lymphatic extension from associated viscera, especially the gallbladder.
2. Toxic damage: poisons, like chloroform, carbon tetrachloride, phosphorus, alcohol; or autogenous toxins like those of eclampsia or intestinal obstruction.
3. Obstruction: common duct blocked by stone, tumor, or stricture.
4. Metabolic states: so-called, concerned with the liver or endocrine organs, predisposing to stone formation.

Infection of the liver through the portal system has its most striking example in pyelephlebitis and liver abscess arising from a suppurating appendix. If major acute infections can derive from this source, certainly minor chronic ones

* A high fat diet in lactating goats does not increase either the milk flow, or the content of fat. When alfalfa hay is added, however, there is an increase in the milk. For lactating and pregnant women a rich diet will probably only give a hypercholesterolemia and lead to gallstone formation. Lean meat and salads furnish the same elements as alfalfa hay.

may, as well as from other gastrointestinal lesions. Proving a connection, however, between infection of the liver and a focus elsewhere through the systemic blood stream is not easy; yet the liver, through its reticulo-endothelial system, is one of the major filters of the body. It is probable that the liver is subject to more or less constant bacterial insult of varying degrees, and it is conceivable that under some of these conditions the liver puts out a bile which is somewhat altered with regard to composi-

with chloroform will markedly reduce bile-salt production. Considerable destruction of the liver has been observed, too, in such conditions as severe puerperal eclampsia and intestinal obstruction.¹⁰ Again Smyth and Whipple have shown that injection of proteose from a closed intestinal loop decreases bile salts. All these conditions, then, would favor precipitation of cholesterol. It is conceivable that industrial poisoning, or mild, long-continued intoxication from food, or food preservatives, or substances elaborated in

Fig. 1.—Cholecystogram of Gallbladder, With Stones. The shadow is clearly outlined and fairly dense, indicating that the mucous membrane has concentrated the radiopaque material. The two rounded areas at the fundus represent negative shadows due to stones of less density than the surrounding medium—cholesterol.

Fig. 2.—Cholecystogram of Gallbladder in Contraction. Same as in Fig. 1, two hours after the patient had taken a meal rich in fats. Note tremendous reduction in size of the shadow. This has been brought about by active contraction of the musculature of the wall. The negative shadows due to the stones are still present. These two figures indicate that a gallbladder may contain stones and yet may function normally with regard to concentration by the mucosa and contraction by the musculature.

tion and chemical relationships; perhaps not enough in itself to cause precipitation, but augmenting a second agent having a tendency to this effect.

Extension of infection to the liver from the gallbladder or another viscus by contiguity, or through the lymphatics, is generally a localized process; it is difficult to see how the character of the bile would be significantly altered thereby. On the other hand, ascending cholangitis with jaundice, especially if repeated, produces a generalized liver damage more likely to affect the bile.

Poisons, such as chloroform, damage the liver severely; also carbon tetrachloride, phosphorus, alcohol, and other chemicals. Chloroform anesthesia of a dog for one hour will produce a central fat necrosis involving one-third of the liver lobule. Smyth and Whipple⁹ have shown that extremely slight poisoning

the digestive tract, or from general toxemia, might disturb the liver enough to alter the character of the bile in such a manner as to favor cholelithiasis.

Obstruction of the common bile duct as a factor in cholelithiasis would have to be incomplete, or intermittent over a considerable period. This could hardly be brought about except by pre-formed stones. In complete obstruction there is eventually an absorption of most of the bile constituents, and, secretion of the liver being stopped, the ducts are filled with mucus and cellular debris. Unless the obstruction is relieved, the individual will die before stones can develop. I have seen, however, in a case of carcinoma of the pancreas, a tremendously distended bile duct and gallbladder containing a material which appeared as if

the pigmented and other solid matter of the bile had precipitated in dark green flocculi, suspended by a clear, thin, mucus-like fluid. The liver showed reddish brown mottling indicating considerable damage.

Finding such a precipitate in simple obstruction with injury to the liver, and no apparent disease of the extrahepatic biliary system, suggests the following hypothesis:

Given *intermittent stasis* due to a pre-formed, ball-valve stone in the common duct, with perhaps incomplete drainage in the intervals, a situation would arise allowing solid matter to collect in the ducts. The liver periodically damaged from obstruction, and more or less continually upset by the processes of resolution and repair, might put out an unstable bile favoring precipitation during the periods of stasis. Some workers¹¹ have found that bile salts in fistula bile are absent or diminished for days or weeks after operative relief of obstruction. This, as previously stated, would dispose to precipitation of cholesterol. Often we see at operation in cases of obstruction by stone a bile loaded to almost putty-like consistency with cholesterol and pigment-containing débris. Infection, also, which usually supervenes in these cases, might be a contributing factor to chemical instability in the bile. Some of these conditions will be discussed later under effects of the gallbladder on the bile in lithiasis.

Here is a promising field for investigation. I hope to be able to continue suggestive experiments started a few years ago, placing human gallstones in the biliary passages of animals, and studying the factors induced by obstruction. I am sure that much could be learned about cholelithiasis in this way, especially if a correlated study be made in patients with gallstones.

Abnormal metabolic states involving the endocrine organs with the liver is also an inviting field for investigation in the etiology of cholelithiasis. Statistics show beyond question that gallstones are more likely to occur in fat persons, and probably in proportion to the degree of obesity.⁴ The rapidly fattening woman with presumable ovarian or pituitary dysfunction, who simply cannot let sweets and rich foods alone, is a good subject for

gallstones. Certain types of individuals, especially those of sthenic habitus, are likely to have gallstones in middle age. Cholelithiasis appears to run in families, a very large proportion of those with the physical characteristics of certain strains developing the disease. It is probably concerned with abnormal fat or cholesterol metabolism in the body and may be related to arteriosclerosis and allied conditions.¹² There is no doubt that in the vast and complicated laboratory of the body processes are going on, of which we know little or nothing, that have a definite relation to the development of stones in the bile.

THE EXTRAHEPATIC BILE PASSAGES, consisting of the ducts and the gallbladder, affect the character of the bile in numerous ways. We assume that their action may be primary, whereby stones are produced in a normal bile, or secondary, by providing means for further alteration of an abnormal bile from the liver.

The ducts, it appears, can modify the bile by addition, by absorption, and by providing a lake for stasis of bile. There are numerous gland-like structures in the wall of the ducts which probably add something to the bile. The purpose of these structures may be simply to furnish a lubricant as the bile passes down from the liver. This function could assume great importance in the passage of a stone. Perhaps Nature saw that her work was imperfect as far as the tendency to precipitation in the bile was concerned and devised this mechanism to assist in elimination of the precipitate.

It has been postulated that these gland-like structures have an absorptive function similar to the gallbladder, and that after cholecystectomy they take over this function.¹³ They are large and numerous in the horse, which has no gallbladder. As stated previously, in prolonged complete obstruction of the common duct the coloring matter of the bile disappears. This may be brought about through precipitation and disintegration of the precipitate, or the pigment, and perhaps other substances may be absorbed by the epithelium of the ducts, including these gland-like structures. The addition of material to the bile, or the withdrawal of material from it, is potentially disturbing to its chemical equilibrium.

The effect of stasis in the ducts is mentioned in the section on the liver. It is illustrated by cases where after cholecystectomy the patient is operated upon time and again for the removal of putty-like débris obstructing the outlet of the common duct. In addition to the factors mentioned in the foregoing tending to precipitation, stasis is added. It is important to note that cutting or dilating the sphincter of the common bile duct at operation would probably prevent the formation and collection of débris. I have observed in numerous experiments on animals that the sphincter does not

Fig. 3—Cholesterosis of Gallbladder With Stones. Represented by Figs. 1 and 2. The serosa is smooth, the wall thin, the mucosa normal except for cholesterosis. The arrow shows a small polyp of the same nature as those in Fig. 10. The lobulated stones were probably made by the matting and rolling together of desquamated polypi as the gallbladder contracted after meals. There could not have been any marked degree of inflammation in the wall of this gallbladder to allow such a degree of contraction as seen in Fig. 2. (From Practitioner's Library, Vol. IV, D. Appleton—Century Co)

regenerate once it is sectioned. We have been fearful that removal of the sphincter would lead to ascending infection of the ducts and liver. The contents of the duodenum, however, are usually sterile. In only the occasional case in animals was there a suggestion of infection, though some were kept for months.

THE GALLBLADDER is an organ, the possibilities of which for bringing about changes in the bile are greater than those of the ducts. It has a structure signifying increased activity, including a larger mucous surface for either addition or absorption of material, and a muscular coat which has the power of expulsion of the vesicular contents.^{14, 15, 16, 17, 18} The mucous membrane is known to produce marked concentration normally in the bile.^{19, 20} This may of itself favor crystallization or precipitation. Aberration in the absorptive or additive power of the membrane may also bring to bear a potent influence in this direction. The complete or partial failure of expulsive action in the muscular coat leads to corresponding degrees of stasis of bile in the vesicle. A combination of these factors multiplies the possibilities for evil. We are not sure that gallstones would be produced from a normal bile under the influence of this altered function in the gallbladder, but it seems a possibility.²¹ It does appear certain, however, that given an abnormal bile from the liver to start with, such disturbances in the activity of the gallbladder will lead to the formation of gallstones.

Let us examine some of these factors:

The *mucous membrane* and conditions associated with it in cholelithiasis will engage us first.

Secretion of the Gallbladder.—It is generally agreed that the mucoid material found in the gallbladder under certain conditions, for instance blockage of the cystic duct, represents a product of its own lining membrane. There are glands in the cystic duct; and it is believed by some that the epithelial cells of the mucosa undergo a process somewhat similar to that of the goblet cells in the intestinal tract. Certainly at times granular and other changes can be seen which indicate secretion.³³ When for any reason bile is prevented from entering the gallbladder it becomes filled with mucoid substance.

Does the Gallbladder Secretion Contain Cholesterol?—For years there has been a controversy over this point. Naunyn²² advanced the idea that cholesterol in the contents of the gallbladder may be derived from the epithelial cells thrown off in normal desquamation, a process which is increased by irritation

from the bile. This increase of the cholesterol content of the gallbladder bile Naunyn believed to be significant in gallstone formation. There is considerable reason in Naunyn's view. We know that all epithelial surfaces exhibit active desquamation. It is a common observation to find a gallbladder where the cystic duct has been obstructed by stone, filled with a mucoid material glimmering with myriads of cholesterol crystals. In many of these cases the mucosa has been destroyed. Possibly the cholesterol crystals were derived from degeneration of the mucosa. Rotating degeneration and regeneration of the mucosa of the gallbladder may lead to a constant increase of cholesterol in the vesicular content. It is, of course, difficult to rule out the effect of increased cholesterol due to inflammatory exudate in such cases. The question arises—does degeneration of the epithelial cells of the mucosa result in cholesterosis? This will be discussed later.

Elman and Graham²³ also hold to the view that the gallbladder secretes cholesterol. Experimentally, they have tied the cystic duct and found at the end of 2 to 16 days that the content of cholesterol in the gallbladder bile was increased. The objection to their experiment is that they must have produced some inflammatory reaction by their blockage of the cystic duct; and we know that inflammatory exudates are rich in cholesterol.

On the other hand, the majority of students do not believe that the mucosa of the gallbladder secretes cholesterol. Aschoff¹² holds that cholesterol is a normal secretion of the liver cells into the bile. Dostal, Hrdina, and Goff,²⁴ and Phe-nister²⁵ found that in cystic duct obstruction the secretion of the gallbladder did not contain an increase of cholesterol.

Several years ago while experimenting with different methods of inducing stasis in the gallbladder, I cut the common-duct sphincter in a number of cats.^{16, 17, 28} In many of them, upon examination after a few days, the gallbladder contained only mucoid material. It occurred to me that, since in these cases the gallbladder did not refill with bile, this would be an excellent atraumatic method for studying the secretion of the gallbladder itself. Dr. Burnham Walker²⁶ and I performed the experiment upon 22 cats. In 18 the results were indeterminate, or the gall-

bladder contained cholesterol, probably from the presence of a small amount of bile, attested by greenish color. In 4, however, the vesicle contained only clear mucus which showed no trace of cholesterol. This led us to believe that the gallbladder does not normally secrete cholesterol.

Boyd³ and Mentzer²⁷ hold that cholesterol is absorbed rather than excreted by the mucosa. I also hold to this view. The evidence in favor of absorption is that solid and lipid materials when placed in the gallbladder can be demonstrated to

Fig. 4.—Cross Section of Gallbladder Wall. Same as in Fig. 3. Low power. Note the large sections of smooth muscle tissue interspersed with fibro-elastic tissue. This muscle was the agent which produced the marked contraction shown in Fig. 2. The fibro-elastic tissue prevents overdistention and rupture of the gallbladder in case of obstruction. Above is the much folded mucous membrane, with large surface for absorption. Concentration of the radio-paque material in Fig. 1 sufficient to produce the dense shadow was made possible by this mucous membrane. The bulbous projection from the mucosa is one of the small "strawberry seeds" in Fig. 3.

have been taken in by the mucosa.^{3, 27, 28} Although actual absorption of cholesterol placed in the gallbladder has never been demonstrated, since lipids are absorbed (Fig. 6), and since Weiser¹ has shown that cholesterol is very soluble in the lipids of the bile, it seems almost certain that this occurs. Wilkie and Doubilet²⁹

have obtained evidence that the content of cholesterol in gallbladder bile depends upon the blood bile-cholesterol ratio. When the ratio in the blood is increased, cholesterol goes into the gallbladder, and vice versa. There may be another cause for this, but, since cholesterol of blood and bile is in the colloidal state, it would hardly seem that the mucosa of the gallbladder could act as a simple osmotic membrane in this case.

The question of variation of calcium content of the bile is, of course, important in cholelithiasis. The majority of workers believe that in inflammation and cystic duct obstruction calcium is increased in the gallbladder,^{22, 25} though some deny this.³⁰

Schubb and Goodstone³¹ report a case with cystic duct obstruction in which the gallbladder contained "milk of calcium" bile. They also review the literature of such cases, and of calcium stone, including those of Phemister. Whether it is by infection, altered secretion, or as Rous, McMaster, and Drury³² hold, alkalization of the bile from these or other causes, aberrations of calcium metabolism in the bile play a significant part in lithiasis.

Selective absorption by the mucosa of the gallbladder alters the content of the bile. Water and soluble salts are taken up as well as more or less solid matter.³³ The mucosa of the gallbladder is generally stained with the coloring matter of the bile, indicating absorption. Lipids are taken up in considerable quantity apparently normally, producing no reactions in the mucosa.^{27, 28} Andrews³⁴ has obtained evidence that in the closed gallbladder bile salts are absorbed much more rapidly than cholesterol, which would tend to throw the latter out of solution. Furthermore, by absorption of water, the bile in the gallbladder is concentrated from 10 to 20 times or more.^{19, 20} Concentration is limited by the fact that the gallbladder continually secretes mucus and empties more or less completely after a meal; there is also considerable overflow of bile upon distention of the vesicle during fasting. However, any considerable increase in concentration of the vesicular content probably favors crystallization and precipitation, leading to formation of gallstones.²¹

Under abnormal conditions the addition to, and absorption from, the vesicular content may be modified. Inflammatory exudate increases the content of cholesterol²¹ and probably calcium.¹² Irritative action upon the mucosa, if mild, may result in an increased expulsion of mucus. If an intense infection supervenes the exudate will be purulent. In blockage of the cystic duct the secretion of mucus continues, augmented by irritation. There is an absorption of pigment from the bile, and later disintegration of the mucosa. Should the blockage of the cystic duct continue, interfering with the circulation of the vesicle, the

Fig. 5.—Histology of Cholesterosis. High power. Showing the bulbous projection from the mucosa, of Fig. 4. The white areas indicate histocytes laden with cholesterol. Continued deposit of this substance produces degeneration of the epithelium by pressure (top); also encroachment upon the blood vessels, with degeneration of the mass³⁶; and thus perhaps an augmentation of cholesterol production. Continuation of this process results in the condition shown in Fig. 10.

process goes on to acute inflammation and gangrene.³⁵ But if it is partially or temporarily relieved, a considerable part of this abnormal content, rich in protein, cholesterol, and calcium, may be left in the gallbladder, with admixture of bile furnishing material for the formation of stones.

Cholesterosis (strawberry gallbladder) is a condition in which the mucosa contains an excessive amount of cholesterol; we do not know whether it is in process of secretion, or absorption, or degeneration. Cholesterol or cholesterol

ester is held chiefly just underneath the epithelial cells, in histocytes, which are connective-tissue phagocytes associated with the reticulo-endothelial system. These may collect into such large masses that they produce small polyps on the mucosa, which give the appearance of strawberry seeds (see Figs. 3, 4, 5, 6, and 10). As we have mentioned, some hold that this cholesterol is a product of degeneration of the mucosa itself,²² or of secretion by the mucosa,²³ and others that it is absorbed from the bile containing an abnormally large amount of it.^{3 27} Normal absorption might produce the ordinary strawberry gallbladder, but it

an over-laden blood, but it does not rule out the theory that it can be caused also by absorption from the bile.

Whatever its cause, *cholestercrosis probably has a direct bearing on the formation of certain types of gallstones*. The theory of Boyd⁴ is that these polypoid masses break off the mucosa in the course of natural desquamation and become rolled and matted into masses which eventually become stones, chiefly of the mulberry or lobulated type. This seems reasonable to me. Examine Figs. 9 and 10. Compare the structure of the polyps and the lobulated masses on the surface of the gallstones in these figures. The spherical shape of this type of stone is evidence that they are produced by agglomeration and rolling of the mass of foreign material into balls by the motion of the gallbladder and pressure of its wall as it contracts (see Figs. 1 and 2).

The collection of cholesterol in the histocytes, or fixed connective-tissue phagocytes, is well illustrated in Fig. 5, the light spaces within the stroma representing histocytes containing cholesterol or cholesterol ester. Figure 6 shows a fat stain giving us an indication of the amount of this material which collects in the mucosa of the gallbladder.

When these masses of mucosa containing cholesterol break off there is, of course, considerable organic matter from the mucosa involved in the material which goes to make up the type of stone under consideration. Figure 14 shows a pure cholesterol stone which at one end contains a mass of the nature shown in Fig. 9. It appears to have been pressed over the end of the stone to which it adhered, and was then polished off by friction of the walls in contraction. To me this is evidence that these lobulated or mulberry stones are produced by agglomeration of smaller masses, the material being derived from the mucosa in cholestercrosis.

What Is the Relation of Inflammation to Cholestercrosis?—It has been held that the process is a direct result of inflammation due to infection.^{8, 23} Evidences of inflammation in the wall of the strawberry gallbladder can be found, but often so slight as to be of doubtful significance.^{4, 25} (Figs. 7 and 8). The gallbladder in this condition usually functions extremely well, both from the point

Fig. 5. A fat stain in the mucosa of the gallbladder. The light spaces in Fig. 5 are stained black here. (From W. Boyd, Brit. Jour. Surg.)

seems hardly possible that it could account for polyposis where there are large masses of the material (Fig. 10). This is more likely a pathological change associated with abnormal metabolism.

Sacks has found that a finely suspended emulsion of cholesterol injected intravenously is deposited in the reticulo-endothelial system; and "Chalatow was able, by especially abundant and protracted stuffing with cholesterol dissolved in sunflower oil to produce lipoid infiltration of the epithelium of the gallbladder."¹² This is evidence that the reticulo-endothelial system is a normal defensive mechanism against cholesterol in certain forms. It suggests that strawberry gallbladder may be produced simply by extraction of cholesterol from

of view of absorption by the mucosa, and contraction of the muscular coat (see Figs. 1 and 2). It is probable that this inflammatory reaction comes as the result of the cholesterosis and not as a cause of it. Picking up of the cholesterol by the histocytes is evidence that it is an irritative material being disposed of by the tissues. Lymphocytic infiltration, the usual result of inflammation in these cases, is another sign of a mild irritative agent. It would appear that if infection with the resultant inflammation were a primary process there would be more disturbance of the normal functioning both in the mucosa and in the muscularis.

A study of the reaction to foreign material in the wall of the normal and inflamed gallbladder has been made by H. H. Cooke.³⁶ Cooke regards the histocytes, which are interspersed among the connective-tissue cells of the wall of the gallbladder, as a definite protective mechanism against bacteria and other foreign matter:

"The injection of particulate matter [very finely divided suspension of carbon particles] or of vital dyes directly into the wall of the gallbladder of the dog produces a rapid mobilization of the resting wandering cells into large actively mobile phagocytic histocytes. . . . In chemical cholecystitis [produced by intravenous injection of Dakin's solution] the histocytes are present in large numbers. They rapidly phagocytose particulate matter, cholesterol, and olive oil injected into the wall. The arrangement of the histocytes in three concentric layers [corresponding to the connective-tissue layers] suggest their function as a phagocytic, cellular, defensive mechanism in cholecystitis and other pathological conditions of the gallbladder."

In view of all these facts it would seem that the following is the most plausible explanation of cholesterosis in relation to gallstone formation. Through overeating of fats, the rapid oxidization and mobilization of fat in the body, or some toxic, metabolic, or endocrine disturbance, hypercholesterolemia is produced. There is a tendency of the reticulo-endothelial system, including that of the gallbladder, to take up the excess cholesterol. Also the liver secretes a bile containing an abnormally high percentage of cholesterol with insufficient bile salt to hold it in solution. This bile collects in the gallbladder, which through some fault of its emptying mechanism is subject to stasis. The actively absorptive mucosa takes up the precipitated particles of

cholesterol. These being irritative are phagocytosed by the histocytes (Figs. 5 and 6), collecting in large masses, forming the typical strawberry-seed polyp on the mucosa (Figs. 3 and 10). The polyps enlarge through the addition of more cholesterol-laden histocytes, possibly from degeneration of the normal cells of the mucosa, possibly by deposition of cholesterol from the blood. They finally break off; and through the motion of the gallbladder during its contractions are rolled into rounded masses, producing gallstones of the mulberry or lobulated type (see Figs. 1, 2 and 9). The evidences of inflammation in the gallbladder beyond the collection of lipid-laden histocytes;

Fig. 7.—Musculature of Gallbladder Wall. High magnification. Same gallbladder as represented by Figs. 1, 2, 3, 4, and 5. Practically the whole field is filled with smooth muscle tissue, giving an idea of the large amount in the wall of the gallbladder; which makes possible such a contraction as shown in Figs. 1 and 2. There is no abnormal infiltration of inflammatory cells—no damage.

that is, the collection of lymphocytes, plasma cells, etc., are due to the reaction on the part of the gallbladder to a mild irritant in its wall. Infection may play no part in the process whatever until, through irritation of the mucosa by the stones ulceration is produced, or by their impaction in the cystic duct, the circulation of the vesicle is disturbed.

For future reference it may be well to bring to mind here the *action of the*

muscular coat of the gallbladder and its abnormalities in relation to cholelithiasis. The purpose of the muscularis is expulsion of the vesicular content.^{14, 15, 16, 17, 18} Note the amount of smooth muscle in Figs. 4 and 7. The fibro-elastic tissue of the gallbladder is to prevent overdistention or rupture. Normally the human gallbladder expels anywhere from one-half to nine-tenths of its contents after an ordinary meal. In fasting or in conditions under which the food is not absorbed, such as

Fig. 8.—Infiltration of Inflammatory Cells. One of the rare high-power fields showing lymphocytes, polynuclear leukocytes, and plasma cells. This indicates a mild process which in all probability has not been concerned in the formation of the gallstones or the cholesterosis shown in Fig. 3. Possibly it is an indication of an irritative reaction due to the presence of cholesterol in the wall of the gallbladder.

nausea, or in low physical states, such as typhoid fever, or in any condition in which the normal stimulus fails to reach the muscle of the gallbladder, it will not contract, and the gallbladder will not empty. If the muscularis is damaged by infection or inflammation (Fig. 11), or if the cystic or common duct is obstructed, the gallbladder will not empty. A stone occasionally blocking the cystic duct may produce a considerable degree of stasis in the vesicle (Fig. 12). Any condition in which the bile remains an abnormally long time in the gallbladder, allowing increased concentration, and perhaps addition of abnormal materials, predisposes to gallstone formation.

The relation of infection to gallstone formation in general is of sufficient importance to merit separate discussion. Gallstones form in the bile and from the bile. The only way infection or any other agent can produce them is by altering conditions in such a manner that solid matter is produced in the bile. To affect the mucosa, which is in contact with the material from which stones are formed infection would have to be severe. For it is a common observation that in all those cases except where inflammation is pronounced, infection in the bile is rare, while in the wall of the gallbladder it is more common. About the only way this infection in the wall of the gallbladder could produce gallstones in the bile would be by damaging the musculature and mucosa to such a degree that they functioned abnormally, inducing stasis and altering the chemical nature of the bile. In this case the inflammation and not the infection would be the direct causative agent. (Experimentation has shown that damage to the wall of the gallbladder interferes with the function of its musculature.¹⁹) It hardly seems conceivable that the amount of inflammatory reaction shown in Figs. 7 and 8 could be directly responsible for the formation of gallstones (unless it were concerned with that other process, *i. e.* cholesterosis), and in the great majority of cases of cholelithiasis inflammatory reaction in the vesicle is slight.

To be sure, some workers have produced gallstones experimentally by infection of the gallbladder, either injection of bacteria into the blood stream or directly into the wall,²⁷ but such methods do not necessarily indicate a natural process. The significant point may be the induction of stasis by damage to the musculature.

The work of others, notably Denton²⁵ minimizes the rôle of infection in gallbladder disease and incidentally in cholelithiasis. In the study of 1,000 specimens he has come to the conclusion that the so-called acute cholecystitis is due chiefly to a mechanical cause, a stone impacted in the cystic duct. This interferes with the lymphatic and venous drainage of the gallbladder, producing pronounced congestion, edema, and at times leading to gangrene. Even so, the evidence of infection in these cases is almost nil.

Denton holds that if infection were a causative agent, one should be able to demonstrate bacteria in the wall of the gallbladder by staining methods in a fair proportion of the cases. This he could not do.

To be sure, blockage of the cystic duct may develop an inflammatory reaction, throwing out a protein-rich exudate into the lumen of the gallbladder, which is concerned in colloidal changes involved in gallstone formation; but I wish again to point out the difference between infection and inflammatory reaction. We may find bacteria in the wall of the gallbladder which has been contracting and otherwise functioning normally, though, of course, a massive infection might lead to acute inflammatory reaction, crippling of the musculature and stasis. As previously mentioned, often there is in cholelithiasis no marked evidence of inflammation, even with tremendous stone formation. The stones themselves, however, may irritate the wall of the gallbladder as it contracts, producing ulceration and possible secondary infection, resulting in a chronic inflammatory process leading to marked fibrosis. This happens with a solitary cholesterol stone or with stones formed through cholesterosis of the gallbladder.

Naunyn²² was one of the first to advance the theory involving infection as a cause of cholelithiasis. He held, however, that stasis from some other cause was a necessary agent predisposing to invasion chiefly of the *Bacillus coli communis*; perhaps through a backflow of duodenal contents via the common bile duct. This produced a "stone-forming catarrh." The deleterious action of the bile on the mucous membrane of the gallbladder contributed to this catarrh, resulting in a disintegration of the mucosa, its degeneration, with the production of cholesterol, finally resulting in an amorphous mass of cholesterol and organic debris which was the mother substance of gallstones.

Aschoff,¹² however, disagrees with Naunyn's theory that cholesterol (and also calcium) which goes to the formation of gallstones can all be produced in the gallbladder as a result of infection and degeneration and emphasizes other factors. He points out that numerous experimenters have found that increase of cholesterol in the food will result in

an increase in the blood, and finally excretion of a larger relative quantity in the bile. As evidence against the production of cholesterol by the gallbladder he cites the work of his pupil, Torinomi, who ligated the cystic duct in animals and examined one-half the bile before, and the other half several days afterwards, finding no increase of cholesterol on the second examination. Aschoff further points out that in the cases where there is a solitary pure cholesterol stone there is usually no evidence of inflammation of the gallbladder. There must then be some other explanation for the formation of such a stone. He notes that Dewey has produced cholesterol stones by feeding of large amounts of cholesterol to rabbits. Chalatow, also, by stuffing cholesterol dissolved in sunflower oil produced lipoid infiltration of the epithelium of the gallbladder. Then, too, Torinomi's experiment showed absorption rather than increase of cho-

Fig. 9.—Agglomerate Stones. Photograph taken for detail of the stones in Fig. 3, in all probability formed by agglomeration of broken-off masses such as that indicated by the arrow in Fig. 3, and those in Fig. 10. These masses have become rolled and compressed into balls by the contraction of the gallbladder, indicated in Figs. 1 and 2. Note the marked similarity of the lobulated masses, and of the polyps in Fig. 10. The surface of the stones is slightly worn by friction one upon the other during contraction of the gallbladder.

lesterol by the gallbladder. Aschoff draws the conclusion that the pure cholesterol stone must be due to some disturbed metabolism consisting of increased secretion of cholesterol by the liver, and its crystallization in the gallbladder. In starvation, for instance, due to breakdown of the bodily fat, there is an increase of cholesterol in the bile. Stasis of this overloaded bile in the gallbladder may lead to precipitation, especially if there is a diminution of the bile salts.

Aschoff expresses the belief that infection, or inflammatory disease, such as brought about by impaction of a stone

in the cystic duct, produces the so-called "infectious stones." With blockage of the cystic duct, hydrops of the gallbladder is produced. If the stone lets up, bile flows in, and changes the colloidal system by mixing with the inflammatory exudate. A precipitation of bilirubin cholesterol calcium results. If there has been a single cholesterol stone previously, crystallization occurs on this stone resulting in what is called a "combination stone" (Fig. 13); if not, precipitation occurs in masses with the formation

Fig 10—Marked Polyposis of the Mucosa. An exaggerated form of cholesterosis. The gallbladder itself is not severely diseased. These masses probably break off and become rolled into balls, such as the stones in Fig. 9, by contraction of the gallbladder. (From S. H. Mentzer, Archives of Surgery, Jan 1927.)

of faceted stones. All these stones originate in a medium rich in protein and consequently have a protein frame work in their structure. The protein may be derived from leukocytes, disintegrating epithelial cells, serum, or fibrin. Since the inflammatory exudate is high in calcium, this is incorporated in these mixed "infectious" stones.

According to Aschoff, pure pigment stones, which form almost always in the gallbladder, are also of a metabolic and not infectious origin. They are hard, brittle, mulberry-shaped—not generally layered. Aschoff admits that their ex-

planation is difficult, but I will emphasize that a sufficient stasis of bile in the vesicle is essential.

One of the best pieces of evidence I have found against infection as a primary factor in cholelithiasis is the specimen illustrated in Fig. 11. There was a congenital deformity of the hourglass type equally dividing the vesicle into segments proximal and distal to the cystic duct. Presumably the constriction induced stasis in the distal segment, which favored precipitation at an earlier period, giving old stones and a sclerotic wall; while the more favorably situated proximal segment showed young stones and early disease. In view of the mechanical reason for stasis here, it seems to me very unlikely that, with the same blood and lymph supply (though perhaps less adequate distally), the essential factor in-

Fig 11—Advanced and Early Disease in the Same Gallbladder. An hourglass (congenital) deformity. The wall of the segment distal to the cystic duct is thickened and shows loss of the mucosa with trabecular scarring. No bile was present. Stones number 2 and 3 were found here. They are of the same type as those in Fig. 9, and were formed in the same way, almost surely on the basis of cholesterosis. They show the same lobulation, but also evidences of friction against the wall of the gall-

bladder against each other. The stasis in the distal segment is due to mechanical irritation by contraction of the gallbladder upon these stones. The proximal segment shows cholesterosis. It contained young, soft, mixed stones—1, 4, and 5, and normally concentrated bile. The significant feature in this specimen is the constriction, which induced stasis early in the distal segment, leading to stone formation, with advanced sclerotic changes, while the freer emptying of the proximal segment delayed the progress of the disease there. The specimen offers good evidence against the theory that infection is a primary cause of gallstones, since both segments have the same blood supply and lymphatic drainage. (From Practitioner's Library, Vol IV, D Appleton—Century Co)

volved could possibly have been infection.

Whether the primary condition is cholesterosis, general metabolic disturbances, liver changes, or infection of the gallbladder, practically all students of this subject have agreed that *one factor necessary to gallstone formation is stasis*, either in the ducts or gallbladder. This has become more obvious in recent years since we have discovered that the human gallbladder empties itself partially or completely after ordinary meals.³⁸ If it functions normally in this respect, there is little opportunity for the collection of debris in the gallbladder leading to cholelithiasis. Unless the cystic duct were very small the cholesterol crystals, epithelial debris, leukocytes, and what not, would be expelled along with the bile after eating, and an influx of fresh

Fig. 12.—Ball-valve Stone in Gallbladder. Cholecystograms showing a contracting gallbladder with a stone of the same nature as those in Figs. 1, 2, and 9; probably produced by cholesterosis. On the left is the resting gallbladder; on the right, the gallbladder contracting after a meal, tending to impact the stone in the cystic duct (arrow). This produces biliary colic. By pressure it interferes with venous drainage; also emptying is prevented, with accumulation of mucous, distention, and ischemia, finally resulting in acute inflammation. Alternate blocking and refilling, mixing bile with exudate, favors precipitation from the bile¹ and deposition on the stone, as in Figs. 13 and 14.

bile several times a day would keep the vesicle effectively flushed.

I have produced in cats hard, black masses similar to gallstones simply by inducing stasis in the gallbladder through fasting and dehydration. The animals were kept under barbital anesthesia, neither eating nor drinking. After 5 to 15 days there were numerous fine particles in the concentrated bile of the gallbladder, varying in size from dust to 1 to 2 mm., and varying in consistency from semisolid to solid.³⁹ By cholecystograms I have demonstrated lack of emptying for one week in the gallbladders of dogs during simple fasting,

illustrating the fact that the vesicle tends not to empty if for any reason the normal digestive stimulus is lacking.

Stasis of bile in the gallbladder as a predisposing factor in cholelithiasis may be brought about in numerous ways.

Anomaly of structure either in the gallbladder, in its relation to the liver, or its peritoneal attachments, may in all probability interfere with its emptying. In Fig. 11 is an example of congenital deformity resulting in disease through interference with function. Stasis was produced by the constriction, leading to stone formation and secondary inflammatory

Fig. 13.—A Giant "Combination" Stone. It measured 5 by 10 cm. The central stone is seen, the other masses having peeled off in desiccation. The original was a solitary, crystalline cholesterol stone. Then material like that in Fig. 9 became impacted upon it, seen at the top of the central mass. Afterward, during stasis and inflammation, other bile constituents were deposited upon the surface,¹ making the single giant "combination" stone. It was contained in a giant gallbladder, as large as a small stomach. The stone ("believe it or not") was impacted in the ampulla. The gallbladder behind the stone contained nearly a pint of highly concentrated bile with numerous particles of what appeared to be the same material as that which had collected on the surface of stone. This illustrates three phases of gallstone formation. First, the solitary, crystalline, cholesterol stone; second, addition by cholesterosis (as in Fig. 14); third, addition by deposition of precipitated matter from the bile, in this case due to blockage of the cystic duct as shown by Fig. 12.

changes. Abnormal peritoneal attachments (which are common) include the so-called transduodenal bands.⁴⁰ These structures, made of thin sheets of tissue like the peritoneum, may extend from the margin of the gastrohepatic ligament over onto the gallbladder or liver beyond, down across the second part of the duodenum to the lateral abdominal wall, or to the colon. Sometimes the gallbladder

itself is attached to the liver by a mesentery. Changes in relations of the gallbladder to the ducts, or possibly a torsion where the gallbladder is abnormally free, may induce stasis. Sometimes torsion of the gallbladder produces a condition analogous to blockage of the cystic duct by a stone—pronounced edema, inflammation, and even gangrene.⁴¹ It is conceivable that repeated torsions spontaneously relieved would produce repeated in-

Fig. 14.—Specimen Illustrating Factors in Stone Formation. Slightly enlarged. The only stone in the gallbladder. The original was a solitary, crystalline cholesterol stone, indicated by the wide central band. The top is capped by material produced in cholestercrosis similar to that of Figs. 3, 9, and 10. While this material was yet soft, the solitary stone, by repeated impaction in the ampulla upon contraction of the vesicle, pressed it over the end, where it became adherent. At operation the stone was found impacted in the ampulla, having produced interference with the circulation enough to cause acute cholecystitis. At the other end of the stone is a deposit of bile-stained material. The probability here is that the stone, impacted in the ampulla, filled most of the gallbladder as it contracted, leaving the bottom end hanging free in the bile at the fundus. Two processes have occurred: deposition of material from concentrated bile on the bottom end of the stone; and, coincidentally, solution of the cholesterol crystals of the original stone by the lake of bile at the fundus—indicated by a sharp line of erosion (arrows). This is evidence that solution may occur, presumably by the bile salts. Certain conditions may favor deposition, others solution, of cholesterol.

flammatory exudation into the lumen of the gallbladder, mixing with the incoming bile when the obstruction was relieved, bringing about a condition favorable to the formation of mixed cholesterol-calcium-bilirubin stones with a protein base.

Also, failure of the normal physiological action of the musculature of the gallbladder for any reason, such as lack of the adequate stimulus, whether it be through the sympathetic nervous system or through the effect of some hormone, leads to stasis. Any condition in which the digestive system is inactive, such as anorexia, may react unfavorably upon the gallbladder; especially since the absorption of some food material, *i. e.*, fat, seems to be necessary to emptying.^{10, 23} In bodily states, like typhoid fever, with all the vital forces at a low ebb, including the digestive system, it would seem entirely possible that the gallbladder could go days and weeks without emptying. If at the same time the character of the bile were altered by the condition of disease, it is easy to suppose that gallstones might be formed simply from the altered physiology of the biliary system, and not at all necessarily from infection. Furthermore, if the typhoid bacilli happened to be present in the lumen of the gallbladder, as elsewhere in the body, they might be included in the mass forming into gallstones. This would explain their presence without assuming an active rôle in the process.

Inflammation of the gallbladder from any cause, when it reaches the stage to prevent the normal contraction of the musculature, will automatically induce stasis. This may occur either in the acute inflammatory process or in the chronic case exhibiting marked fibrosis. It makes no difference what the original cause, whether infection from some other focus, or coming as a result of cholestercrosis, or following the blockage of the cystic duct by a stone, or from irritation of stones in the lumen—inactive musculature means stasis.

Occasionally we find a gallbladder which during the Graham test does not empty for hours, perhaps even a whole day, after the administration of one or more fat-rich meals. This, of course, is decidedly abnormal and would theoretically predispose to cholelithiasis. If the emptying time is greatly prolonged, we are always suspicious of a stone blocking the cystic duct. Upon rare occasions a patient is found in whom, under the Graham test, the gallbladder is not observed to fill, even by the intravenous method, yet at operation the vesicle contains nor-

mally concentrated bile and gives no explanation for the lack of filling with the opaque material. The few patients in whom this occurred were in rather poor physical condition. The probability is that the stimulus to emptying had not been adequate, the bile had remained in the gallbladder, become concentrated, and, since the gallbladder was distended with concentrated bile, there was no room for entrance of bile containing the radio-paque material.

The older books have a good deal to say about lack of exercise, tight lacing in women, etc., being predisposing factors to stasis in the gallbladder. This idea is based upon the mechanical theory of emptying; that is, that the vesicle empties from pressure by descent of the diaphragm with respiration, by increasing intra-abdominal pressure through muscular action, etc. It has been adequately proven physiologically that the gallbladder does not empty this way.^{16, 17, 18, 38} Therefore, these are not direct factors in stasis. To be sure, lack of exercise or other unhygienic mode of life might reduce the physical condition to the point where the bodily processes were not working normally, including the musculature of the gallbladder. Since the gallbladder empties by its own contraction, any factor which induces stasis outside of the obstructive conditions, acts by interfering with the action of its musculature. I repeat that a normal gallbladder expels from one-half to three-fourth of its contents, possibly more in some cases, after an ordinary meal. If this happens two or three times a day, it does not seem possible that stones can form in the gallbladder. What matter if there are a few masses of desquamated epithelial cells or free-floating crystals of cholesterol in the bile of the vesicle, or even bacteria or inflammatory débris, when these are pushed out regularly by vigorous muscular contraction.

On the other hand, considering the static gallbladder as a test tube containing an abnormal bile, it is interesting to see what changes might occur leading to cholelithiasis. One of the most important investigations on this question has been made by Dr. Harry B. Weiser,¹ who has produced *artificial gallstones by the methods of colloidal chemistry*.

Weiser recognizes the commonly ac-

cepted fact that cholesterol is held in the dispersed (colloidal) state in the bile by the peptizing action of the alkali cholates, but points out the additional fact that cholesterol is much more soluble in fat than it is in a solution of bile salts. For instance, in an 8 per cent solution of sodium glycocholate, held for several days at body temperature, 100 c. c. took up but 0.2 gm. of cholesterol, whereas 100 c. c. of olive oil dissolved 8 gm.

"Since the bile may contain 1 per cent or more of fatty material it is apparent that one-third to one-half the cholesterol in normal bile is dissolved in the emulsified fat. Moreover . . . any excess cholesterol tends to concentrate around the fat droplets. [It is pointed out in this connection that bile salts have an indirect action by emulsifying the fat.] When the droplets of fat are coated with a film of cholesterol there is a marked tendency to form clumps of droplets. . . For the formation of large cholesterol crystals from the minute particles (collected around the fat droplets) it is necessary for the emulsifying film of sodium glycocholate to be broken so that cholesterol can come in contact with the saturated fat droplets. Under such circumstances it would be expected that the minute particles would dissolve and reprecipitate out in larger units. There proved to be two relatively simple methods of breaking the glycocholate film on the droplets. First, adding a trace of acid which converts the glycocholate to glycocholic acid, which is not an emulsifying agent; second, allowing the sample to dry thus causing the film of hydrophylic emulsifying agent to crack."

Weiser performed such an experiment, which resulted in the formation of large feathery cholesterol crystals adherent to the fat droplets. He separated this fat-cholesterol mass by centrifuging, then "after absorbing the excess fat with blotting paper the mass was formed into a ball and dried. The result was a relatively hard, crystalline mass simulating the natural pure cholesterol stones in appearance, composition and properties. . . In the light of the above series of experiments the mechanism of the formation of cholesterol stones in the absence of inflammation due to infection is believed to be as follows: In bile stasis resulting from anatomical [see Fig. 11] or physiological abnormalities [previously discussed] the bile collects and concentrates in the gallbladder, where it may remain for a long period. During this period of stasis there may be an infiltration of cholesterol from a hypercholesterolated blood, and a decrease in the amount of alkali cholates which are responsible for retaining the fat in the form of an emulsion as well as the cholesterol in the dispersed state. In the absence of infection a decrease in alkali cholate may result from either or both of the following causes: (1) A change in the pH of the bile, from the alkaline to the acid side, thereby converting the alkali salts to the insoluble glycocholic acid, which is neither an emulsifying agent for fat nor a peptizing

agent for cholesterol; or (2) a physiological change in the gallbladder wall which allows resorption of the alkali cholates. . . The disappearance of alkali cholates either by conversion to glycocholic acid or by resorption, causes precipitation of cholesterol. This is, of course, most marked in highly hypercholesterolated bile. The excess cholesterol collects around the fat droplets, which tend to coalesce as the cholates are gradually removed. Clumps of fat interspersed with cholesterol result, and the process of solution of the finely divided particles and subsequent reprecipitation in large needle-like crystals binds the mass together. The continuation of this process for a long period leads eventually to the concrement which consists of relatively large crystals of cholesterol together with a small amount of enclosed fat. . . Particular attention should be called to the importance of fat in the synthesis of pure cholesterol stones. Not only does it serve as a collecting agent which brings together the particles of precipitated cholesterol, but its solvent action is responsible for the growth of the interlacing crystals. Since the bile contains no solvent for cholesterol except the fat, the presence of the latter is essential in the formation of pure cholesterol stones."

The stones in Fig. 9 represent those formed by another process; that is, the agglomeration of masses of desquamated epithelium containing cholesterol. If these stones are broken open one will find that there is a crystalline structure in the interior of a radiating character. It appears that according to Weiser's findings the probable explanation of this crystalline interior is that, since the forming mass contains more or less bile along with degenerated epithelium, there would be considerable fat. This would facilitate recrystallization of cholesterol in the interior of the stone, leaving the outside, however, in the original condition, exhibiting the masses of material as they were broken off from the mucous membrane.

Weiser also reproduced experimentally the so-called "infectious stones."

"The marked inflammation accompanying an infection in the bile ducts or gallbladder introduces into the bile irreversibly precipitating hydrophylic colloids such as serum albumin, globulin and fibrin. If cholesterol or calcium bile pigments separate in the presence of such colloids there is mutual adsorption with the result that the whole is united into a coherent mass, giving what is sometimes termed a colloid-crystalline stone as distinct from the pure crystalline stone considered in the last section. . . Adsorption of the bile pigments or their precipitation as the calcium salts stains the stone [Figs. 13 and 14]. . . The so-called calcium salt of the bile pigment is probably an adsorption complex of indefinite composition. . . Obviously the inflammatory process introduces numerous nuclei on which the mixture of

cholesterol and hydrophylic colloids will collect. Because of the pressure of the gallbladder the stones are seldom spherical, but are faceted and usually of widely varying shapes."

By the methods of colloidal chemistry Weiser produced experimentally the layered or banded mixed stones, explained in this way:

"From a survey of the conditions which result in the formation of the so-called 'layered' stones and the experimental results given in the previous section, it would appear that the formation of such concretions is favored or initiated by inflammation, which yields irreversibly precipitated protein material, such as fibrin and albumin. Pathologic changes bring about precipitation of the cholesterol, carrying calcium with it, the nature of the precipitate depending upon the amount of hydrophylic colloid present. Into this mass the colloiddally dispersed bile pigments diffuse and are precipitated in the form of rhythmic bands. The structure and arrangement of the bands are influenced by the shape of the mass, its density due to the pressure of other stones, and by variations in the composition of the bile fluid. After the bands are formed the structure may be invaded by radial crystallization of the cholesterol, cracks may develop, further deposition of the cholesterol may occur, or the stone may undergo alteration in other ways, producing the wide variety of forms which are found in gallbladder disease."

SUMMARY

The first essential in cholelithiasis is a bile from which the materials of gallstones readily separate—one which becomes so altered that solids are not retained in solution or colloidal dispersion.

Cholesterol is the chief substance concerned with gallstones; it is held in dispersion by the action of bile salts and bile fats. Excess of the cholesterol, lack of the salts and fats or changes nullifying their action, allow precipitation.

Hypercholesterolemia, due to conditions such as pregnancy, diabetes, or endocrine disturbances, leads to excess of cholesterol in the bile.

Disturbance of the liver, from infections, toxic damage, obstruction, or metabolic states, may so alter physicochemical relations in the bile that crystallization or precipitation occurs.

For stone formation a lake of bile is necessary—furnished by obstruction or stasis in the ducts or gallbladder.

Stasis in the gallbladder is induced by failure of the musculature through lack of adequate stimulus or from inflammation, as well as obstruction by stone.

Inflammation as a result of primary

infection may occur, but it usually follows obstruction or irritation by stones.

Infection is more often secondary to stones produced through metabolic disturbance and stasis, than primary.

Cholesterosis (strawberry gallbladder), probably the result of hypercholesterolemia, metabolic disturbance or the liver and dysfunction of the gallbladder, leads to the formation of agglomerate stones. Inflammation, always slight, seems to be secondary, not primary.

Artificial gallstones, resembling those of pure cholesterol, and layered stones of the so-called "infectious" type, have been produced in vitro by the methods of colloidal chemistry.¹

In man the essential conditions for gallstone formation are a bile in which there is a tendency to crystallization and precipitation; and a static extrahepatic biliary system furnishing a lake in which the necessary physicochemical changes may occur.

This paper undertakes to give a concise discussion of the main trends of thought upon gallstone formation. The rôle of infection is minimized; and that of metabolic and chemical changes, and stasis, emphasized. The mechanism of stasis is described.

CORONARY THROMBOSIS—SOME POINTS IN THE DIAGNOSIS AND PROGNOSIS

ROBERT H. HALSEY, M.D.

New York, N. Y.

Since this topic was selected for discussion two men of great prominence in national politics have passed out of public life with the newspapers reporting death as due to "acute indigestion."

This misnomer continues to be employed, though the localization of the symptom—pain—on which it is based has long since been proven to be caused by the asphyxiation of the cardiac muscle, or infarct, following a thrombosis in a coronary artery. And yet I am sure many physicians have in their care patients who have had similar accident; in fact, some physicians have been victims and are now the living proof of the fact that there is a hopeful outlook and future for those who may have experienced such an accident. Because of the frequency of the condition and in the hope that a discussion of the topic might be fruitful I was persuaded to undertake the presentation of some of the main points.

Let us return for a moment to consider the situation as it was when, at a meeting of the College of Physicians, July 21, 1768, William Heberden read his paper in which he said: "There is a disorder of the breast, marked with strong and peculiar symptoms, considerable for the kind of danger belonging to it, and not extremely rare, of which I do not recollect any mention among medical authors. The seat of it, and sense of strangling and anxiety with which it is attended, may make it not improperly be called angina pectoris.

"When a fit of this sort comes on by walking, its duration is very short, as it goes off almost immediately upon stopping. If it comes on in the night, it will last an hour or two; and I have met with one, in whom it once continued for several days, during all which time the patient seemed to be in imminent danger of death.

Time and attention will undoubtedly discover more helps against this teizing and dangerous ailment; but it is not to be expected, that much can have been done toward establishing the method of cure for a distemper hitherto so unnoticed, that

it has not yet, so far as I know, found a place or a name in the history of diseases."

As we reread these abstracts it is evident that Heberden described two distinct types of attacks and to-day these are grouped under two diagnoses. In one, the pain begins and increases steadily and progressively with continued effort and decreases promptly with rest. In the second the pain comes on and persists, even though the victim may be at rest. In this brief way Heberden described the two common phases of coronary artery disease, but the distinction in his description of the onset and course does not appear to have been recognized in his often quoted first description. It required nearly a century and a half before differentiation and distinction of the two pictures was recognized and the pathological etiology established. It is, therefore, only continuing the confusion and can serve no good purpose to speak of "Heberden's angina" when intending thereby to convey the idea that pain comes on with exertion and passes with rest, as contrasted with pain that persists even when at rest—Heberden described them both. But in those days the difference in pathology had not been discovered. Nor should one fail to recognize that pain is the early symptom of blood-volume incapacity of the coronary artery even if unassociated with the "sense of strangling and anxiety" which Heberden recognized and emphasized by selecting the Latin word "angina." But the free translation, a sense of impending dissolution, indicates a symptom which is not present in all cases of coronary disease either with or without thrombosis. It is difficult to visualize the pathology of conditions which have no cardiac symptoms, yet are dubbed "angina" by some authors; and yet it seems most important to approach the subject from the standpoint of etiology.

TYPICAL PICTURE.—The typical clinical picture of an attack of coronary thrombosis which has emerged includes five

points: (1) a history of a rather startling and surprisingly sudden onset of a persistent increasing discomfort often becoming a real pain in the sternal region; (2) this is usually accompanied by some degree of definite circulatory shock; (3) within a few hours some fever (rectal temperature 100° F. or over) develops; (4) a leukocytosis (10,000 to 20,000 or more) is found; and (5) within a day or two, if carefully searched for, may be heard a pericardial friction rub, which is usually of brief duration.

AGE AND SEX INCIDENCE.—Usually the patient is a man in the sixth decade or older, less commonly in the fifth, and rarely in the fourth decade or younger. From one-third to one-half have hypertension. It is rare to have a woman present the picture, but they do have the disease, and its recognition should not be refused nor the situation confused by calling it "pseudo-angina."

PATHOLOGIC PHYSIOLOGY.—Coronary thrombosis is a complication of coronary artery disease which is often revealed in two stages: the first, by breathlessness on exertion, and the second, by sternal pain on exertion. Atherosclerosis may be general or accenuated in the coronary arteries. The function of these arteries is to supply the heart muscle with a sufficient quantity flow of blood at all times and particularly when the extra demands of exertion are made. To supply oxygen and carry away the products of muscle activity by increased flow may be within the capacity while the patient is quiet or sitting, but when disease has decreased the quantity flow, then muscle action quickly absorbs the oxygen and the accumulating metabolic products of action are not removed. It has been demonstrated repeatedly by embolic blocking of peripheral arteries during life, as well as by postmortem findings in the heart, that pain, severe and persistent, results from the cessation of blood flow in muscle which is contracting. It is assumed that the minute flow of blood must be increased to meet the demands of increase exercise. It is, also, assumed that the arterial capacity flow can be increased by the acceleration of the heart rate. But, in disease of the arteries, the capacity is reduced and first there is dyspnea only; then, as the decrease in functional capacity

continues, a point is reached when even with acceleration the flow is insufficient, and it is insufficient for such a period that both an anoxemia and an undue accumulation of waste products result. At this time there is pain. The reduction of circulatory demand by rest permits the decreased flow to once more supply all the requirements.

These assumptions help us to understand the history of the attacks of pain. Infarcts and healed scars of old infarcts, are found in many hearts without any previous clinical or subjective symptoms having been recognized, probably because the onset was slow and progressive.

THE PAIN.—In describing sensations each patient selects such words as come within the range of the personal vocabulary and are in sympathy with the introspective nervous reactions. There will be the term indicative of low intensity of discomfort, while another may appear to suffer acutely and with a high degree of apprehension. It is important, therefore, that the apparent and visible reaction, or the vigor of the language in which the complaint is couched does not mislead in an estimate of the degree of damage. Thus the absence of fear of the result, or absence of the "angor animi" of the older authors, should not be considered confirmation of the noncardiac origin of the complaint. Some patients appreciate pain much more keenly and have a much wider vocabulary than others—patients may be hyper- or hyposensitive as well as better informed in choice of words.

In eliciting the story of the attack it is very important to encourage the patients to describe the condition in words of their own selection and relate the order of events immediately preceding, at the time of, and subsequent to, the attack.

Thus the terms used may describe merely a discomfort or a pain as burning, dull, sharp, or stabbing in character. Or the feeling may be one of pressure, or of compression, or it may be even exploding in character. Sometimes it is a strangling or threatened shutting off of the breath, and then it may be associated with the fear of impending dissolution—the "angor animi" mentioned above.

The onset may be of low intensity or severe, but usually it increases in severity to its height in a few minutes, which may be agonizing, then gradually re-

gressing. But it usually requires hours or days to disappear. It is important to recognize the persistent character of the pain and that it does not have the periodic or rhythmic recrudescence that so often accompanies injuries of the abdominal viscera.

Superficial Area Involved—It is helpful to let the patient outline with his finger the area at which the pain was first felt and its enlargement or direction of radiation. Usually the discomfort is felt first at the lower gladiolus, the ensiform, or epigastrium, less frequently at the manubrium, and as it increases in intensity, it usually spreads to the left pectoral region, the left shoulder or arm, and wrist, the left side of the neck, and thence to the left interscapular. Often there is radiation to the right shoulder and arm or it may be felt on both right and left and sometimes over the whole anterior thoracic region of both sides. The pain may be referred to the upper abdomen.

The head zones may be sensitive and easily outlined and, as the acuteness of the symptom subsides, the area may be the site of diffuse soreness.

Reaction to Pain—The patient may react to the attack of pain by remaining quiet, and it has seemed to me that this is usually true if there has been a former period of pain on effort. In other patients there may be restlessness and actual pacing the floor in distraction. If the attack is severe, some patients very soon become evidently critically ill and haggard in appearance. This is true particularly of those with the greater degree of shock.

ASSOCIATED SHOCK—With the onset and development of the attack of pain vomiting may occur, and there are usually varying degrees of circulatory shock, such as pallor, tremor, accelerated heart action, and a cold clammy sweat.

FEVER—The estimation of fever should be made only on rectal temperatures. These findings may show no increase or only a rise of a degree or two for a day or two. If a large infarction has occurred, it may be accompanied by a temperature remaining for a week or longer. There are many patients who have a clear history of infarction and subsequent pain on effort and yet do not show temperature, pulse, leukocyte, or electrocardiographic changes.

THE LEUKOCYTOSIS—The leukocyte count in very mild cases may not be disturbed, however, when the count is over 10,000 and under 20,000 the volume of heart muscle involved is assumed to be less than if the count is over 20,000. That is, there is assumed to be a relation between the volume of the muscle impaired by the occlusion and the leukocyte count. If the count persists for several days, its continuance is considered indicative of a greater injury than when it subsides in a few days.

In estimation of the relation of counts and degree of injury it is essential that a pneumonia or pulmonary infarction can be excluded.

PERICARDITIS—The pericardial rub is usually heard below the third rib and between the sternal edge and the apex. It may be heard for a few hours only or may persist for two or three days. It has a definite relation to the size of the infarction, and while it persists, the temperature, pulse rate, and leukocyte count are increased.

PULSE RATE AND RHYTHM—The radial pulse may not be altered at first, or occasionally it may be slowed, but usually it is accelerated and returns to the previous rate only after several days. The volume of the pulse is small and often difficult to feel or count.

The rate may vary and the rhythm remain regular throughout the period of the illness and convalescence. Less rarely there may occur a new mechanism, as auricular fibrillation, or flutter, auriculo-ventricular block, and still more rarely ventricular tachycardia. The onset of a new rhythm may obscure the recognition of the real accident—the thrombosis of a branch of the coronary.

BLOOD PRESSURE—Usually with the onset of the thrombosis the blood pressure falls promptly. In some hypertensive patients there may be a difference of over 100 mm of mercury before and after the occlusion. Occasionally there is a fall of only a few points, but it is not uncommon to have the systolic pressure fall below 100 mm.

If the pain is acute, there may be a rise of pressure followed by a fall on the relief of the pain. As restoration occurs, the pressure may return to its former level.

The low systolic pressure may be an indication of the greater gravity, but I have seen men with a systolic reading under 75 mm. gradually recover to become ambulant patients with several years of life.

It is probably correct to state that attacks of pain on effort are associated with a rise of pressure but the occurrence of thrombosis is accompanied by a fall in systolic pressure.

ELECTROCARDIOGRAPHY.—The electrocardiogram will be most helpful if taken systematically in frequent series as it may show definite changes which are positive evidences. However, there are coronary accidents which do not show alterations in the electrocardiogram early but do show changes later and vice versa, and sometimes there are no changes in the electrocardiogram either early or late. We must conclude, therefore, that the electrocardiogram may be considered positive evidence, but the absence of changes does not preclude a coronary accident.

The occurrence of auricular fibrillation or bundle branch block seems to add to the seriousness of the outlook.

The changes in the S-T deviations of Lead I have been ascribed to the occlusion in a branch of the left coronary and the S-T changes of Lead III are associated with right coronary occlusion, but since these arteries do intercommunicate and are not limited to the right or left lateral portions of the heart, the interpretations of the deviations must not be too specific. The use of special leads in addition to the standard leads, may be of great value in confirmation of the condition.

CORONARY ACCIDENTS WITHOUT PAIN.—The sudden onset of congestive failure—venous congestion, enlarged liver, edema of the ankles—in an elderly man or woman, in the absence of some definite infection or other condition which might affect the circulatory system, should suggest a coronary accident; and, if associated with the onset of nocturnal dyspnea, cardiac asthma, and Cheyne-Stokes' periodic breathing (not three separate symptom entities, but only three names for phases of the same disorder), should strengthen the suspicion and cause a search for more evidence—pericarditis, leukocytosis, and electrocardiogram.

EMBOLI.—Once a coronary artery is blocked, the effect is the formation of a

myocardial infarct which in turn may produce blood clot formation in the right or left ventricle, or in both. Fragments from these coagulated masses in the right ventricle may be broken off and carried as emboli into the pulmonary circulation causing a pulmonary infarct, sudden chest pain, dullness, auscultation changes, and x-ray shadows, and occasionally expectoration of bloody fluid. Clots formed in, or carried through, a septal defect into the left ventricle may be carried as emboli into the spleen, with left-sided pain; kidney, blood cells in urine; brain, impairment of the mentality, vision, or motor function; arm or leg, cyanosis and gangrene, with characteristic symptoms. The sudden onset of these indications of localized alterations of function should suggest the probable etiological pathology.

DIFFERENTIAL DIAGNOSIS.—The discomfort of thrombosis is not relieved by nitroglycerin as is the coronary disease with pain.

It is with the intention of describing the etiology that there are such qualifying diagnoses as neuritis, pleurisy, intercostal neuralgia, and acute indigestion which indicate inflammatory or painful conditions of the nerve trunk and pleura or functional incapacity of the digestive tract. Such diagnoses should be carefully and critically analyzed before acceptance.

SPONTANEOUS PNEUMOTHORAX.—Rarely a spontaneous pneumothorax may occur with such sudden and severe pain referred to the lower precordium and associated with shock—pallor, tremor, profuse perspiration, cold skin surface, rapid pulse and dyspnea—that a coronary accident may be suspected. X-ray examination of the chest and electrocardiograms may clear the picture.

CHOLECYSTITIS AND CHOLELITHIASIS.—Severe pain referred to the lower chest and upper abdomen with muscle tenderness and rigidity, nausea, vomiting, and shock suggest an acute abdomen as well as coronary thrombosis.

The previous history of the character of the pain, whether it recurred on effort, was referred to the left shoulder, left elbow, and left shoulder blade, and whether there is a sense of chest constriction, will indicate its probable coronary origin. If it occurs in a man over forty-five with other

evidence of general arteriosclerosis, it is more certain.

But if there is a previous history of long-standing colonic distention and flatus with periodicity of attacks and reference of the pain to the right shoulder blade, the gall-bladder should be suspected. If the patient is a woman under forty-five who is, or has been, obese, cholelithiasis is probable.

A duodenal or gastric ulcer which has ruptured is more common in men under forty, while a ruptured gastric carcinoma may occur in the age group over fifty.

COMBINATION OF CORONARY DISEASE AND CHOLELITHIASIS.—It is not easy to make the distinction or be satisfied that gallstones are present in a man or woman who gives the symptoms of both gallstones and pain with effort. A period of careful observation may clear the picture and an operation relieve both sets of symptoms.

OTHER ACUTE CONDITIONS IN THE ABDOMEN.—Tabetic crises may confuse at first but the history of the mode of occurrence and the physical findings should quickly bring assurance of the probable pathology.

Acute appendicitis, acute hemorrhagic pancreatitis, acute intestinal obstruction, and thrombosis of the mesenteric artery may each offer a confusing picture. The greatest help in distinguishing between them and a probable coronary thrombosis

may lie in the previous history and habits of the person with the description of the onset of the attack, its relation to shock, abdominal tenderness and rigidity.

PROGNOSIS.—No certain picture is possible, but there is better than an even chance to recover.

The most cheerful figures show that five out of six live through their first attack; one out of four lives more than a year after the attack.

Coronary accidents which do not terminate life within a year give the possibility of a continued and useful life.

A leukocytosis of over 20,000 appearing promptly and persisting several days indicates an extensive involvement of the muscle by infarction and a serious outlook. The infarct may be the site of rupture of the wall any time within the first month.

Severity of pain and behavior of the patient do not indicate the comparable degree of muscle damage, though the great degree of circulatory shock may accompany a greater volume damage.

If after healing the classification is II A or better there may be many years of useful life.

If congestive failure remains with a classification of II B, or worse, the probabilities of life are measured in months.

Cheerful adherence to a rest program of four to six weeks probably prolongs life.

121 EAST 60TH STREET

DOCTOR'S FEE IS NOT A PRICE

The physician should not be led astray in these days of cost-accounting; the doctor charges a fee, not a price, says the *Westchester Medical Bulletin*. It drives the point home by relating one of those stories which are true whether or not they ever actually happened, a story about Whistler which is told by Albert Edward Wiggam. The great painter, it seems, once agreed to appear as an expert witness in a court case involving a question as to whether a certain painting was a genuine work of the artist whose creation it had been represented to be.

As soon as the witness was seated, the attorney, with due flourish, unveiled the canvas. Whistler took one look at it, pronounced it a fraud, and left the courtroom. The purchaser of the painting, at whose request Whistler had appeared, won the case and recovered substantial damages. When Whistler sent her a bill for \$1,000 for his services, his client protested: "How can you charge \$1,000 for the work of an instant?" Whistler's reply was: "I have charged you \$1,000 for the work of a lifetime."

This story illustrated the difference between a fee and a price. A price, of course, is based upon a calculable cost.

Physicians and other professional workers should remember this distinction, says the *Westchester county editor*. They should never attempt to justify any given fee on a cost basis. A professional fee computed on a basis of mechanical costs is not in any sense a professional fee. Those who attempt to standardize medical fees under any guise are laboring under a fundamental misapprehension, and the physician who listens to such an attempt is going to be sold a very costly gold brick.

Before the days of anesthesia, surgeons performed operations as fast as possible, to shorten the patient's agony. As a result, relates Dr. Howard Haggard, some of the more deft surgeons were little short of sleight-of-hand artists. They could amputate a limb so rapidly that close attention was necessary on the part of spectators or they missed seeing the operation entirely.

THE UNIVERSITIES OF THE MIDDLE AGES

DAVID RIESMAN, M.D., Sc.D.

Philadelphia, Pa.

It is customary in certain circles to disparage the Middle Ages, to call them the Dark Ages of history. Such disparagement is, however, scarcely justified. The Middle Ages unquestionably had many shortcomings, many vices, but they had also many virtues. Among the greatest of these virtues was the founding of the universities, the most important factor, the writer believes, in the development of modern culture and in the emancipation of the human spirit. If there were no other contributions on the part of the Middle Ages to civilization, that should insure them our everlasting gratitude. As Rashdall says, the institutions the Middle Ages have bequeathed to us are of greater and more imperishable value than the cathedrals. And the university is distinctly a medieval institution. Its ideals, its organization, its ceremonies, its titles, its offices, its degrees, its costumes even, have been handed down with very little change to modern times. Whatever differences exist are due largely to adaptations to local conditions.

While in this country the original university is legendarily a log with Mark Hopkins at one end and a student at the other, in Europe the universities arose in cities and kept pace with the growth of cities. Protected by the authority of an ecclesiastic or a prince or a self-appointed potentate, scholars could find in these cities leisure, emolument and fame, and in that way they could attract pupils. In Italy, where universities had their most rapid growth, they thrived in cities often ruled by tyrants, by men who combined a humanistic spirit with treachery, cruelty and every vice in the calendar. Even under such a bestial creature as Ezzelino da Romano—there was scarcely ever a more wicked ruler—the University of Padua flourished mightily.

Perhaps it should be explained in the beginning what was meant by the word "university" in the Middle Ages. It did not originally connote a place of higher learning, not a collection of schools or a corporation entitled to confer degrees. The

nearest analogue to our universities was called *Studium generale*. The word "universitas," employed usually with another word in the genitive, designated a corporation in its totality, as for example, *universitas magistrorum et scholarium*—university of masters and scholars. The word also bore an analogy to guild and was used very much like our phrase trade union to-day. As an indication of the significance of the word we have the story that some captives from Pisa imprisoned in Genoa organized themselves into a "*universitas carceratorium*," a university of prisoners.

In the beginning, teaching in what became the university was carried on in the homes of the masters or in places rented by them. In a number of instances, as is mentioned by Dante, the beginning seems to have been in houses of prostitution. At first, masters as well as pupils sat upon straw, the master having one sack more so that he might be able to dominate his hearers. In 1366, the students were ordered to sit upon the bare ground so that they might have "no reason to be proud."

There were, of course, some schools in Europe before the universities. They were known as cloister or monastic schools and as cathedral schools. Some of the cathedral schools, such as those of Tours and Chartres in France and Fulda in Germany, attained great fame. They were the homes of theology, of canon law and of philosophy, but as they were usually identified with a single personality, a famous master, they languished or perished when the master died.

The curriculum in these schools was by no means simple—at least not quantitatively; it comprised the two great courses of study so characteristic of the Middle Ages, the Trivium and the Quadrivium, the former being made up of arithmetic, grammar and music, the latter of dialectic, rhetoric, geometry, astronomy. Even to-day one finds frequent references in literature to the "Seven Liberal Arts" of the Middle Ages. Much research has been

expended on the chronology of the universities in order to arrange them in order of priority. With one exception such attempts have failed because the rise of nearly all the earlier institutions is veiled in obscurity. Of only one can we say with some assurance that it was first, and that is the School or University of Salerno.

Salerno enters the academic world picture at a very early date. Neither the time nor the manner of its founding is known, but unprovable legend ascribes it to the fortuitous meeting of four learned men, a Roman, a Greek, a Jew, and a Saracen. Some believe it owes its origin to the monks of the neighboring Monastery of Monte Cassino, but although the Benedictines may have had an influence upon the school it is unlikely that they founded or controlled it. If they had it would not have been under a dominantly lay influence—twenty-three out of thirty Salernitan professors were laymen. Salerno is important not only as a center for teaching but also because it preserved the Greek writings and had a share, largely through the mysterious Constantine the African, in introducing Arabic learning into Western Europe—and we owe a greater debt to the Arabs than is generally known. Another fact is interesting, namely, that the University of Salerno had the first definite medical code, very much like our NRA codes, and perhaps received with equal acclaim. It demanded five years of study with an examination at the end, and the doctors were enjoined not to make any compact with the apothecaries. Salerno never became a general university. It was soon overshadowed by neighboring Naples, although it lived on with fame dimmed until 1811 when Napoleon in conquering Italy put a finish to it.

Among the Salernitan writings that have come down to us, none is more renowned or better known to moderns than the *Regimen of Salerno*, a metrical medical work containing sound advice as to diet, bleeding, and ways of life in general. Few works in the history of the world have been copied and recopied and printed and reprinted more often. The poem has a special interest for us for it was dedicated to the King of the English. But who that was is uncertain; many assume it was Duke Robert of Sicily, son of William the Conqueror.

One of the earliest universities and one that still exists is the University

of Bologna, which had its hazy beginning sometime in the twelfth century or toward the end of the eleventh. It arose largely through the fame of two persons—Pepo and Irnerius—who were both great legal scholars and attracted a multitude of students. In 1158 Frederick Barbarossa, Emperor of the Holy Roman Empire, granted to the students of Bologna two important privileges: freedom of travel and freedom from civil jurisdiction. The freedom of travel was particularly important in that it created in Europe the wandering scholar who traveled from place to place in search of knowledge and became such an attractive medieval figure.

The two privileges enjoyed by the students, together with a third, the right to choose their own masters, gave to Bologna a stronger lay influence and a greater freedom than prevailed elsewhere. These features extended to other Italian universities founded afterwards; they have never entirely died out, unless at the present time things have been changed in Italy.

Foreign students came to Bologna from all over Europe, the wandering scholars, at one time eighteen nations were represented there. The foreign students organized themselves into the University of the Ultramontanes, the Italians into that of the Cismontanes. It is interesting that the Bolognese students themselves had no right to vote and could not hold office.

Bologna at all times was a university of students. The students were dominant; not only did they select their masters, they held them to strict accountability. The professor who refused to take the vow of obedience to the students had no means of collecting his fees. He might not be absent without leave a single day. If he had an audience of less than five, he was fined as if he were absent. He had to begin at the sound of the bell and had to stop one minute after the sound of the next bell. He was not allowed to skip a difficult text or to postpone it for the next lecture. In other words, he had to punch the clock.

There was for years much opposition in Bologna to the establishing of a medical university. Finally, in 1306, it was accomplished and the university of medical students obtained the right to elect its own rector. But Bologna remained primarily a University of Law. In Bologna, as in Oxford in Paris and elsewhere, conflicts were frequent between the citizens and the students, between town and gown. One of

these recurring conflicts led to the emigration of some students and masters from Bologna; they settled in Padua and established a school there.

"Travio, since for the great desire I had To see fair Padua, nursery of the arts, I am arrived for fruitful Lombardy"

says Lucentio in "The Taming of the Shrew." Shakespeare knew Padua, the nursery of the arts, because many of his countrymen had gone there to study. Padua like other cities of Italy during the Middle Ages was the football of warring tyrants. When one studies the history of this turbulent period, when destructive and centrifugal forces held sway, one must admire the more the magnificent works of Mazzini, of Cavour, of Garibaldi, and of Victor Emanuel in unifying these disjointed states and making of Italy a great nation.

The writer has been much interested in the paradox not only manifest in Padua under the treacherous Carraras, but also in Milan, Florence, and other cities, that the worst tyrant was at the same time the most enlightened patron of art. Perhaps it is only history repeating itself when we see some of our grafting politicians and dishonest bankers filling their palatial homes, built with other people's money, with costly works of art.

Padua's fame began with the advent of a man known as Pietro d'Abano, called also the Conciliator because he wrote his medical articles in the form of "concilia," or consultations. He was an astrologer and a follower of the Arabs, in particular he was a so-called "Averrhoist," which in his day was tantamount to being a heretic. In fact, he was twice haled before the Inquisition and twice acquitted—a very rare event in the history of the Inquisition.

A legend has it that when d'Abano lay on his deathbed, he told his students and fellow physicians that he had devoted his life to three noble sciences, one of which made him subtle, and that was philosophy; the second made him rich, and that was medicine (that was in the Middle Ages); the third made him a liar, and that was astrology.

Padua was a more liberal university than most of the others, due perhaps to the fact that it started as an Averrhoistic school. Although a papal edict had commanded that non-Catholics should not be admitted to study at Padua or to receive degrees, the command was more honored in the breach

than in the observance, and a number of men, Protestants and Jews, received their diplomas at Padua, for example, William Harvey, Richard Mead and John Kaye, the Caius of "The Merry Wives of Windsor."

It was through Thomas Linacre, a graduate of Padua before Henry VIII's apostasy and one of the founders of the Royal College of Physicians, and a few other humanists that the Italian influence came into England so strongly during the Tudor period. The reader may remember, Queen Elizabeth was called the Italianate Queen; and the scenes of many of Shakespeare's plays are laid in Italy.

Among the great Italians who studied at Padua was Girolamo Fracastoro, the man who wrote the most famous medical poem in the history of the world, the poem on Syphilis or Morbus Gallicus. Another Italian graduate was Fallopius, after whom the Fallopian canal of the ear and the oviduct are named, and Harvey's teacher, Fabricio d'Acquapendente, the discoverer of the valves of the veins. Jerome Cardan, mathematician and physician, Malpighi, the discoverer of the capillary vessels, and Galileo, one of the greatest minds produced on the Italian peninsula, are also in some measure identified with Padua. We, the possessors of the English civilization, must not forget our debt to that small Lombard City.

Another early medieval university, by some considered the oldest of all, is that of Montpellier, the ancient Mons Pistillarius, so-called by reason of its commerce in spices. Its founding is credited to a group of Jewish physicians from Spain. In the early days there were frequent conflicts between the Judeo-Arab physicians from the Iberian peninsula and the Christian physicians educated chiefly at Salerno. However, in 1180, the reigning Duke William IV promulgated a decree that anyone whoever and of whatever origin he might be should have the right to give medical instruction without being called to account by anyone. Although the teachers at Montpellier had to be celibate, the spirit of the University was on the whole fairly liberal. Jews, except during temporary periods of intolerance, were allowed to teach there. Among such teachers the names of Jacob ben Machir and Samuel ben Tibbon have come down to us.

In 1220, Cardinal Conrad, descendant of a Swabian family, promulgated statutes

that contributed markedly to the growing fame of Montpellier. He laid it down as a law that no one should act as a teacher of medicine who had not been examined in it and had received the license at the hands of the Bishop of Maguelone, and that no one should be regarded as a student who did not in his studies follow the directions of his teachers. The rule regarding examinations applied however only to physicians and not to surgeons. Every student had to attend medical lectures for at least five years and was obliged to practice medicine for eight months or for two summers before being allowed to graduate. In 1350 the Master's degree was made a requisite for those who wanted to practice medicine. To achieve the doctorate, the candidate was required to pass sixteen examinations which were held by the professors in secret and were very costly. By the time the student attained the doctor's degree he had expended a little fortune, originally 16,000 francs, in time reduced to 8,150. In later years after the candidate had passed the examinations successfully, the beadle clothed him with a special red robe called the *Rabelais*. His comrades then, each in turn, gave him a sharp blow with the fist, an ancient custom much imitated in later ages.

Montpellier achieved its greatest triumphs in the thirteenth and fourteenth centuries.¹ The monk Caesarius of Heisterbach called it the "Fountain of Wisdom" and regretted only that the doctors did not believe in miracle-healing and would speak of it in an ironical manner. It had among its pupils and teachers men like Raymond Lull, Bernard of Gordon, Arnald of Villanova, Gilbertus Anglicus, John of Gaddesden, and most famous of all, Guy de Chauliac. Its decline to some extent was due to the religious wars, and the cupidity of the townspeople, but chiefly to the rise of Paris and of universities in Germany and Italy. In the early part of the sixteenth century it enjoyed a brief second blooming in consequence of the sojourn there of the incomparable *Rabelais* (1530 and 1539). But even in later times it was frequented by a number of famous medical men—Sydenham, Vieussens, Sylvius, Bauhin, Barthez, Grasset, and the botanists Sauvages and de Candolle.

The writer now asks the reader to travel northward to the river Seine, to the City of Light. The University of Paris is more interesting in its rise and development, more important to civilization than any other in the world. Its beginnings are undatable. Some say it was founded by Charlemagne or by his adviser, Alcuin, an Englishman, but there is no proof of that. If any one man may be looked upon as the founder of such an institution as the University of Paris, that one is Abelard. Abelard was in all respects a great scholar and a characteristic medieval product, a keen dialectician and an independent thinker, a crooked stick that fitted nowhere. He has, however, achieved, in a sense at least, an unwarranted fame, due to the fact that he was beloved by the gentle Heloise. She was a much finer person, the writer believes, than her lover.

Abelard had a tremendous following, wherever he went crowds of students accompanied him, and in that way, through the large numbers that came to Paris to listen to Abelard and to others, the University began. Unlike Bologna it was from the beginning a university of masters, not of students, a circumstance that had a tremendous influence upon its subsequent development. The forces in Paris were centripetal, while in Bologna they were centrifugal.

Paris was always under ecclesiastical control. The Pope was the supreme head of the University and at all important functions was officially represented by the Chancellor of Notre Dame. This absentee control continued well into modern times. Early in the thirteenth century, the Masters of Law, of Theology and of Medicine organized themselves into separate faculties with a dean at the head, it is then that the word "*facultas*" or faculty first was used. The Faculty of Arts had as its head a Rector who eventually became the dominating influence in the university. Both masters and students were compelled to be celibate—they were clerics and had the tonsure. Celibacy continued to be obligatory until 1452, when Cardinal D'Estouteville abrogated it, saying it was impious on the part of a doctor to be compelled to be celibate. The permission, however, applied only to the masters, the students were not allowed to marry. When, as occasionally happened, a married

¹Henry of Montpellier was called to attend Eleanor, Edward I's Queen in her illness and accounted on October 18, 1290, the sum of 13s 4d on account of syrups and other medicines purchased for the Queen.

student applied for his degree, he was rejected.

The students were a polyglot group who quite early in the history of the University organized themselves, for protection and for sociability, into four Nations—the English, the French, the Piard, and the Norman. In the fifteenth century, England became so unpopular in France that the English Nation thought it tactful to change its name to German. There is very little known about the inner workings of these four Nations. Only one thing has been revealed in late years—there is a new book on this subject—that is, the taverns they visited “in the habit of drinking up the surplus.”

Almost from the beginning, Paris attracted the most brilliant men in Europe who came to study and often remained to teach. Roger Bacon, one of the greatest names in English history, Albertus Magnus, Petrus Hispanus, afterwards Pope John XXI, the only medical men ever to occupy the papal chair; and St. Thomas Aquinas, called the greatest pure intellect of all time, were contemporaries at Paris. No wonder the University counted its students by the thousands.

The University of Paris, like similar institutions elsewhere had little real property and therefore had no board of trustees; there was no extramural body in control, as there is in our American universities.

The teaching of medicine in the University of Paris was in the hands of the Faculty of Medicine, an arrogant, intolerant, closed corporation endowed with important rights and privileges granted to it by the Kings of France and by the popes. The members were privileged to wear the long robe; the surgeons, who were not members of the Faculty and could not be, were permitted to wear the short robe, and the barbers who were the minor surgeons, were not allowed to wear any robe at all.

The instruction in the Faculty was in Latin and Latin was compulsory on the campus outside the classroom. It was said that only plowmen and swineherds and other rustics used the mother tongue. As the teaching and practice of surgery was not permitted to clerical persons and as clerics were the only learned men, surgery of necessity fell into the hands of the unlettered, into the hands of barbers or “barbitonsors,” as they were called. The fact that surgery started among the unlettered had a great influence upon surgery in

France and in England and unquestionably retarded its progress. In England to-day the separation survives to some extent—surgeons are very often called “Mister”—and not Doctor. Two other features served to accentuate the differences between the physician and the surgeon: First, the social status of the surgeon was much lower than that of the physician. Secondly, the medical men had a great many more saints. Their patron saint was St. Luke, but in addition they had as many as two or three saints for every disease, while the poor surgeons had only two really important sainted patrons—St. Cosmas and St. Damian. On account of this fact, they were always taunted by the medical men about their poverty in saints.

From records kept by the Faculty—the writer has in his possession an original Latin work—we know a great deal about the customs and regulations of the medical course. The Dean of the Faculty, though he was nominally subject to the first physician to the king, had in reality tremendous power. He was elected with elaborate ceremonies for one year. Coins were struck which carried the Dean's or the President's image or his coat of arms, a privilege, say the records, granted to the Dean before the memory of man.

The course of instruction was long and rigid. Work began at five o'clock in the summer and six o'clock in the winter, and there were four degrees or grades—bachelor, licentiate, master, and doctor. In the beginning a Master of Arts degree was not necessary, but as such a degree shortened the course, most students strove to acquire it. In 1426, over five hundred years ago, the Master of Arts degree became a definite requirement for the study of medicine.

At first the actual course of study was 32 months, but beginning with 1350 the Faculty required 36 months for those having the arts degree, 48 months for those not having it, and if the student came from a foreign university, the time was doubled. Anyone failing once was not afterwards eligible for a degree. Before being admitted to the examinations, the student had to swear that in case he failed, he would not avenge himself on his masters.

The examination began at five in the morning and lasted until noon, refreshments being served then at the candidate's expense. The examination was oral and consisted of questions on texts of Hippoc-

rates and Avicenna and in dialectical arguments. Here are some of the questions found in the book previously mentioned and in others: Is the loud voice warm? Is air, food, or drink a greater necessity?

There was also another examination which was called "quodlibetaire"—what ever you please. The student could virtually designate what he wanted to be examined on. Two grades were given in the examination—*sufficiens*, *incapax*. Two-thirds of the votes were necessary for a man to pass.

The Bachelor, after having gotten his degree in Paris if he wanted to go to higher degrees was obliged to engage in practice for two summers if he lived in the city, for two years if he lived beyond. Many bachelors remained to teach, somewhat like our "Fellows" to-day; their courses were called extraordinary courses, while those of the professors were called ordinary courses.

For the licentiate degree, four special courses were necessary—three had to be medical, one might be nonmedical. For reasons that are not apparent, many students for the nonmedical text chose Aristotle on animals and meteors. The student was admitted to this examination if he could prove he had studied in Paris 56 months, if he had the M.A. degree, and 68 months if he did not have the M.A. degree.

Before he could enjoy the newly acquired rights and privileges, the candidate had to receive official and religious consecration from the Canon of Notre Dame, a very formal, solemn function. Prior to this consecration, he had to pay courtesy calls on the Chancellor, on the heads of the church, on all of the professors, on the higher officials of the state, on the members of Parliament, and to make presents of sweetmeats to all the doctors—a very expensive obligation. Afterwards these costly sweetmeats were replaced by jetons or tokens, one for each professor.

On the Sunday following these preliminaries, the ceremony of "paranymphy," or "paranymphia," took place. It was a symbolic function in which the licentiate was united with the faculty, the dean being the paranymph, or, as we would call him today, the best man, at the wedding. The principal ceremony consisted of a very fulsome Latin oration in praise of the masters.

The doctor's degree was not obligatory, but most men took it. The examination was called the vesper. A few days later

the examination having been completed, the candidate, clothed in robe and fur-trimmed hood and accompanied by two Bachelors and two beadles, paid a visit to each doctor. Finally, he had to swear the following oath:

1. To observe faithfully the secrets, honor and practice, customs and duties of the faculty with all his power and no matter what may happen, never to go against them.

2. To render honor and respect to the dean and to all the masters of the faculty.

3. To aid the faculty against any one who undertakes anything whatever against the statutes or the honor of the faculty and especially against those who practice illegally and to submit to the punishments inflicted by the faculty in case of default.

4. To be present in academic costume at all Masses ordered by the faculty, to arrive at the latest before the end of the epistle and to remain until the end of the office, be it even a University Mass for the dead, under punishment of an "ecu," and likewise under a similar penalty to be present every Saturday at the Mass of the School, vacation time excepted.

This oath, as the reader will note, has nothing whatever to say about the duties of the doctor toward his patients, only about the honor and dignity of the faculty.

One more step remained and that was called the "acte de regence," which consisted in sustaining a thesis publicly. Thereafter the candidate was enrolled among the masters.

Some of the theses that the candidate had to defend were:

Is the necessity of death innate?

Does the fetus resemble the mother more than the father?

Is air more necessary than food or drink?

Is water more healthy than wine?

Is woman an imperfect work of nature?

Should literary men marry?

Religious observances played a prominent part in the students' lives. Masses were frequent—one was held on October 18 on St. Luke's day, the patron Saint of doctors; there was a mass for deceased doctors at which all students were required to be present. Another was celebrated for the repose of the souls of those whose bodies the students had dissected. The students and faculty were also compelled to attend and to take part in all processions in honor of the king or any of the king's

relatives. On St. Luke's day there was always a banquet and those who failed to be present were deprived of the right to carry a candle on what was called Purification Day. Banquets were held when the dean's appointment was ratified; when the roster was finished; in fact there was a succession of gastronomic solemnities that weighed heavily on the student's stomach and budget. This perhaps explains the penchant of our own time for medical dinners and banquets; they have an ancient lineage.

Now a few words about the statutes pertaining to surgeons. Surgeons could not aspire to the grade of doctor; if they did, they had to forswear absolutely by solemn oath their profession of surgery. Though eventually privileged to wear the mortar board and robe, they were not entitled to the benediction of the Chancellor of Notre Dame. Only in 1579 did they obtain that privilege from Pope Benedict XIII. There were constant quarrels between the surgeons and the barbers who were taking their trade away. The barbers wanted to do all the minor operations, and the medical faculty for purely selfish reasons fostered this quarrel, which continued until 1660. In the previous year the surgeons conceived the idea of admitting the barbers to their own corporation. That angered the faculty and they threatened to deprive the surgeons of wearing any robe and of bestowing any kind of degree. This threat brought the surgeons to terms; they agreed forever after to obey the commands of the faculty.

To a large extent, as has been stated, our present-day customs and ceremonies and academic degrees are derived from the University of Paris. Indeed it may be said that the University of Paris is the alma mater of all modern schools of learning, a fact that we should not forget. The history of Oxford and Cambridge is also full of interest and so is that of other early universities that have not been mentioned.

It was indicated earlier in this essay that some writers disparage the Middle Ages. Dean Inge, the Gloomy Dean, called the Middle Ages, "Battles of crows and kites." Another says he is glad he knows nothing of the ages that knew nothing. It is not easy to see why he wants to be so proud of that. Such a contemptuous attitude is in part due to a peculiar phase of cultural life that pre-

vailed in the universities and among the learned in general—it is called scholasticism. This word connotes a form of abstract speculation through which, it was held, all truths, physical and spiritual, could be reached. It was thought possible by a syllogism to arrive at natural truth. Scholastic philosophers concerned themselves more with the formulation of a problem than with a real understanding or solution of it. The method had its origin with the Arabs from whom it was taken over by the great churchmen of the Middle Ages. Anselm of Canterbury, the author of the famous dictum, "Credo ut intelligam"—I believe that I may understand—attempted to establish the truth of the doctrines of the church with such philosophical proofs as, independently of the authorities accepted by believers, would convince nonbelievers of the truth of these doctrines. This special method of argumentation or "dialectic" passed over into the profane sciences, into medicine and into law. Knowledge of natural phenomena could be attained by the mental processes of speculation and of dialectical discussion without any reference to external phenomena or external nature. Words became more important than subject matter, literal text than theme, binding than contents. Hardly anyone thought of testing truth by experiment. Only Roger Bacon had the courage to do this, and in consequence he was a prisoner for many years. The bitterest discussion was on the subject known as "Universalia," the question being in its simplest form: Do general concepts like chair, house, have a separate existence? "Yes," said some and they were called realists. Others said "No, universal concepts have no separate existence, they are -abstractions"—chair does not exist, but a chair exists, a particular chair. The proponents of this doctrine were called nominalists.

The pedantic discussion continued for a long time and is one of the arguments advanced by those who say that the Middle Ages were sterile. But they forget that this type of discussion, this fine-spun argumentation, was not without advantage—it sharpened men's minds and prepared them for the great period we call the Renaissance. But that the method for generations fettered the spirit of inquiry in the universities, especially in the domain of medicine, cannot be disputed.

IRRADIATION OF THE ENTIRE BODY

(Heublein Method)

LLOYD F CRAVLER MD, and WILLIAM S MACCOMB MD

From the Memorial Hospital for Cancer and Allied Diseases New York N Y

Irradiation with x-rays of the entire human body is not a new procedure. Since the early work of Dessauer, in 1905, and of Wetterer, various roentgenologists have exposed the entire body to x-rays, in small intermittent doses, for various conditions, chiefly skin diseases, leukemia, and Hodgkin's granuloma. The methods have varied, but in general rather brief exposures to roentgen rays, at distances of the order of 1 to 2 meters, have been used. The results of such methods have been favorable in many instances.

Certain theoretical considerations and practical observations led the late Dr Arthur C Heublein to form the opinion that to this principle of so-called total irradiation should be added a method of prolonged continuous irradiation with low intensity, short wave lengths, and even distribution throughout the body, in treating those types of neoplastic diseases which tend to spread or metastasize widely. All the above specifications are met in the continuous therapy unit, established with the help of Dr Heublein at Memorial Hospital in May 1931.

The unit (Fig 1) consists of a ward containing 4 beds and having an x-ray tube operating at 185 kv and 3 ma mounted near the ceiling behind one wall, so that two beds are 5.4 meters, the other two beds 7.3 meters from the tube. The filtration is now 2 mm of copper. The intensity of the radiation reaching the near bed is 17 r per hour, that reaching the far beds is 0.9 r per hour. Taking 750 r as the skin erythema dose for a single exposure to ordinary high-voltage x-rays, the time required to deliver 30 per cent of this dose, or 225 r, to a patient in a far bed of the Heublein unit is 250 hours. Averaging 20 hours of exposure a day (time being taken out for nursing care, examination of patients and one half hour daily visiting period), such a dose would consume a period of 12.5 days. To obtain a more uniform distribution throughout the patients'

bodies, their beds are reversed every 12 hours.

It was the hope of Dr Heublein that irradiation of the entire body continuously over a comparatively long period might be carried to a point of sufficient dosage to exercise some satisfactory measure of control over widely metastasized tumor processes. He reasoned from some observations of his own, in which considerable sections of the body had been heavily irradiated, that it should be possible to irradiate the entire body without great damage, and hoped that prolonged continuous application of the radiant energy would yield better results. Naturally the idea of subjecting patients to irradiation of the entire body, involving effects upon the entire hematopoietic, endocrine, and other systems, at first encountered considerable scepticism and aroused fears of unknown and unpredictable consequences. After much discussion it was decided, nevertheless to try the experiment, beginning with a very cautious dose and proceeding gradually to larger doses in suitable cases in an attempt to learn the effect of this type of irradiation on various widespread tumor processes with doses which the body could tolerate.

The selection of patients was guided by two main principles. On the one hand cases of generalized radiosensitive malignant tumors were selected, even though they might appear suitable for the usual methods of palliative irradiation. On the other hand, a selection was made of patients bearing widely metastasized radio-resistant tumors, who were still in sufficiently good condition to offer hope of a satisfactory period of observation. The selection of cases was under the control of a special committee on experimental irradiation. Arrangements were made for complete and accurate control of the patients before, during, and after the treatment. In the beginning not only were careful blood and blood platelet counts made,

but a series of determinations was carried out on each patient, consisting of blood calcium, phosphorus, sugar, nonprotein nitrogen, CO_2 , pH , icterus index, fragility test and basal metabolism. As no significant changes were observed in any of the blood chemistry determinations they were

body of any patient, though it has seemed that an exceptional case might sometime be found for whom a somewhat larger dose might be tried. It seems doubtful, however, that any patient with a generalized malignant tumor will be able to tolerate as much as 100 per cent of an erythema

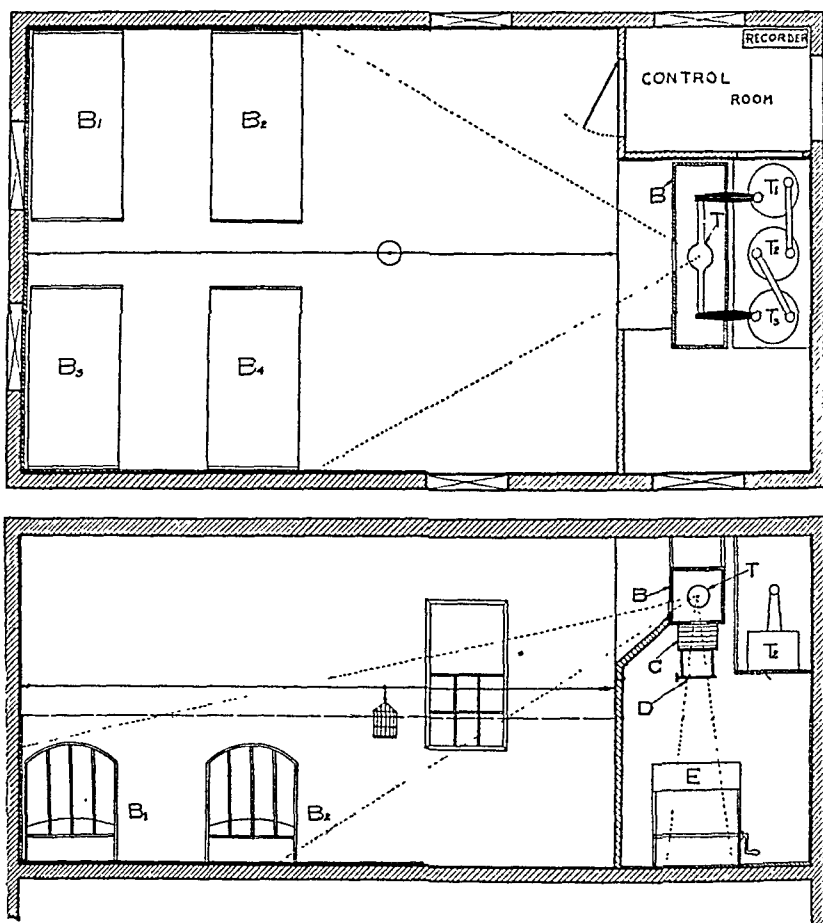

Figure 1.—Floor plan and front elevation of Heublein unit for continuous irradiation of entire body
T = Tube. Beds B_2 and B_4 are 5.4 meters, beds B_1 and B_3 are 7.3 meters from the target. At E is a table directly under the tube, for local irradiation of large fields (maximum portal a circle 27 cm. in diameter) at 150 cm. target-skin distance.

later dispensed with, so that now the main laboratory control consists of blood and blood platelet counts.

The dose used in the beginning was only 5 per cent of an erythema dose. It was found possible as succeeding patients were treated, to increase the dose gradually, keeping in mind always the nature of the disease. Thus, leukemic subjects have invariably been treated with caution. Eventually patients were found for whom doses of 50, and in one case 60, per cent S.E.D. (375 to 450 r) seemed justified. No higher dose has as yet been given to the entire

dose (750 r) over the entire body in one cycle of three weeks.

It is noteworthy that radiation sickness as usually observed with local intensive irradiation is practically absent; nor is there any question of erythema, radio-dermatitis, or alopecia. No consistent effects on the menstrual cycle of women patients have been found, but most of the women treated had either passed the menopause, or they already had amenorrhea as a result of their disease or previous treatment.

The main harmful effect is a decrease in

the white blood cells, which does occur in a large number of the patients, though apparently to no greater degree than is seen in patients who receive large doses by local irradiation. In some there is also a tendency to anemia. These effects are combated when necessary by large whole blood transfusions and in some instances sodium nucleotide has seemed to be of value in counteracting leukopenia.

In the selection of patients, while preferring to choose those who have had no previous irradiation, we have willingly accepted a good many who had been locally

The experience gained over a period of nearly two years, not only in cases treated by this method alone, but even with those patients who also received local irradiation, permits, we believe, certain fairly definite conclusions as to the value of continuous low intensity irradiation of the entire body.

Fig 2—Chronic lymphatic leukemia, October 7 1932. Note enlargement of spleen and liver, and of the cervical lymph nodes.

Fig 3—Chronic lymphatic leukemia, December 28, 1932. Compare with Fig 2 and note reduction in size of spleen and of cervical lymph nodes. The only treatment was irradiation of the entire body.

irradiated, even extensively, if their condition seemed to warrant a trial of this method, we have not hesitated to employ local irradiation subsequently, or even during the course of general body irradiation in cases in which the best interests of the patient demanded that the obvious benefits to be derived from local therapy be not withheld. Such mixtures of treatment naturally render more difficult the appraisal of the method, but we have preferred to rely upon a more gradual accumulation of experience, depending upon close clinical observation of larger numbers over a longer time than would be necessary had we restricted the treatment of all the selected cases to the method of general irradiation alone.

RESULTS—From the latter part of May, 1931, to March 15, 1933, 118 patients

TABLE I—CASES TREATED BY CONTINUOUS IRRADIATION

May 25, 1931 to March 15, 1933

Total number	118
Treated second time	27
Treated third time	7
Local irradiation previously in	67
Local irradiation subsequently in	23

(Table I) were treated by irradiation of the entire body, with doses of from 5 to 60 per cent of a skin erythema dose (including one who received 75 per cent SED to the neck and thorax). Twenty-seven of these patients were treated the second time,

and 7 the third time. The number of patients who had received local irradiation previously was 67, and 23 received local irradiation subsequently. Sixty-two of the patients died. None of these deaths, however, was attributed to the irradiation.

RADIORESISTANT GROUP.—In the group having radioresistant tumors (Table II), such as melanoma and mammary carcinoma, there were 24 patients, of whom 23 died. It should be borne in mind that in all cases of radioresistant tumors selected for whole body irradiation the tumors had so widely metastasized that the prognosis appeared utterly hopeless. One patient

temporary palliation had prostatic carcinoma with extensive metastasis to the skeletal system. He received 60 per cent S.E.D.

TABLE III.—RADIORESISTANT GROUP
Metastatic Mammary Carcinoma

Number of patients (dosage 15 to 50 per cent S.E.D.)	12
Slightly improved, succumbed later	3
Died without improvement	9

RADIOSENSITIVE GROUP.—In the group having radiosensitive tumors (Table IV), there were 94 patients, of whom 39 died. Of those who died, 9 showed temporary improvement. Of the 55 living patients 44 showed definite improvement as a result of general irradiation and are living 1/3 to 20 months following treatment. Sixteen of those who showed improvement are living over 6 months. Eleven of the living patients are unimproved.

TABLE IV.—RADIOSENSITIVE GROUP*

Number of patients (dosage 5 to 50 per cent S.E.D., 1 at 75 per cent to part of body)	94
Improved, living, 1/2 to 20 months (16 over 6 months)	44
Improved, succumbed later, 1 to 13 months	9
Unimproved, living, 0 to 20 months	11
Died without improvement, 0 to 7 months	30

Thus 56 per cent of the patients in the radiosensitive group showed definite improvement and 47 per cent are living and were improved, while in the radioresistant group only 3 patients out of 24 showed slight improvement, and only one patient is living and was improved.

The results in chronic lymphatic leukemia (Table V) have been particularly gratifying. In general our experience with this disease when treated by local irradiation has been less satisfactory, at least much less spectacular than with local irradiation

TABLE V.—LYMPHATIC LEUKEMIA

Died without improvement, 1/2 to 7 months	9

of the myeloid form. While our experience in the general irradiation of myeloid leukemia is limited to 5 cases, our impression has been that the response of chronic lymphatic leukemia is better. It has proved advisable to limit the dose for

* As this work is still in progress, and the results so far are discussed in the sense of palliation, it was felt justifiable to include all cases treated up to the date of the report, March 15, 1933, thus accounting for the short duration of some cases.

Died without improvement	19

method alone; she is still living, 21 months following the first treatment, two periods of treatment having been given to this patient. Four of those who died seemed to have slight temporary palliation.

As an example of the radioresistant group (Table III) may be selected the cases of mammary carcinoma, 12 in number, receiving doses of from 15 to 50 per cent of a skin erythema dose. All these 12 patients died, only 3 showing slight temporary palliation. The other patient in the radioresistant group who showed slight

leukemias to not over 15 per cent S.E.D. (112.5 r), and preferable to use the far beds, so as to administer this dose more gradually. Up to March 15, 1933, 24 patients with chronic lymphatic leukemia were treated with doses of from 6 to 30 per cent S.E.D. Of these, 13 are living from 1 to 20 months following treatment and showed improvement, a palliative result in 54 per cent. One patient who showed temporary improvement died 13 months after the first of two treatments. One patient, still living seven months following general irradiation, showed no improvement, and 9 died without palliation. Our experience in this group suggests that the failures in some were due to overdosage, in others to the disease being in too late a stage, and that in the future we should be able to better these results considerably in selected cases (Fig. 2, 3, 4, 5, 6).

In Hodgkin's disease (Table VI) we have another considerable group with some striking improvements. Of 33 patients,

TABLE VI.—HODGKIN'S DISEASE

Number treated (dosage 5 to 40 per cent S.E.D.)	
1 at 75 per cent to part of body.....	33
Improved, living, 1/1 to 12 months.....	19
Improved, succumbed later, 5 and 12 months.....	2
Unimproved, living, 0 to 20 months.....	6
Died without improvement, 1/10 to 6 months.....	6

19 are living 1/4 to 12 months following treatment and have shown improvement, and 2 of those who died showed temporary palliation. Six are living but unimproved, while 6 died without improvement.

We recently treated one patient with mycosis fungoides who had a generalized erythematous scaling eruption for 15 years and severe itching for one year. He received a total of 15 per cent S.E.D. (112.5 r). Within 24 hours after he had begun treatment, his itching disappeared, and the rash had faded appreciably by the end of his few days' stay in the unit. In this instance the filtration was left at 2 mm. of copper, since the long duration of the symptoms suggested that he might have beginning visceral lesions.

Multiple myeloma appears to be a disease which may to advantage be treated by this method. Of 6 patients with multiple myeloma 5 showed improvement, although 2 subsequently died. Only one of the 6 died without improvement. The improvement in one of the patients following the first treatment was most striking. This patient was greatly incapacitated by the

disease. She was barely able to get out of bed without assistance and required several minutes to do so. She was given 50 per cent of an erythema dose in one of the near beds. The only local treatment given was 700 r to the dorsal spine, one of the chief sources of her pain. Within 2 months the change in this patient's condition was remarkable. She made long trips by motor, and walked about almost normally. Unfortunately she had a relapse several months later, did not respond well to a second treatment and died about five weeks following the second treatment.

In the more radiosensitive tumors, such as lymphatic leukemia, Hodgkin's disease, and multiple myeloma, it is most gratifying to watch the progress of many of the patients while they are in the ward undergoing the continuous irradiation. Sometimes within one or two days the patients themselves state that they feel distinctly better, and in those with lymphatic leukemia they may even in such a short time observe that their enlarged lymph nodes are beginning to regress. While the improvement in the patient's comfort may perhaps be partly ascribed to complete rest in bed and more individual nursing care, in a small quiet ward, in contrast to the usual ambulatory treatment when local irradiation is used, yet the course as a whole during and after treatment leaves no doubt in the minds of observers that the irradiation itself is bringing about a pronounced change for the better. Such observations, coupled with the fact that the very gradual administration of the dose avoids completely the usual acute toxic effects of irradiation, as well as erythema, and the realization that so much of the disease is being treated which would otherwise be missed, make one feel that for some diseases this method is an approach to the ideal therapy.

Yet certain disadvantages must be recognized.

(1) Because of lack of experience with this method it is always a difficult and highly individualized problem to decide what dose to administer to any given patient. We feel that we overdosed some of our leukemics, and believe now that no patient with leukemia should receive over 15 per cent (112.5 r) in one treatment cycle, lasting 6 or 7 days, and that perhaps even this figure is too high.

(2) In some diseases, even the relatively radiosensitive ones, it is probable that the patient will not tolerate irradiation of the entire body in a dose sufficiently great to have the necessary controlling effect on the local lesions. However, we believe that in many cases it may be of advantage to give what is estimated to be a safe dose of general irradiation, and then if necessary use local irradiation, in smaller doses than usual, for such lesions as are troublesome symptomatically or disturbing to the patient because of their con-

would be safe. This hesitancy to use larger doses is partly due to the fact that in the past eight months we practically gave up attempting to treat radioresistant processes such as widely metastasized mammary carcinoma, although we hope that perhaps some exceptional case may yet come along in which we shall feel justified in attempting to push the dose a bit higher.

(3) A rather well-marked leukopenia has occurred in some cases, sometimes associated with considerable lassitude and weakness.

Fig 5—Lymphatic pseudoleukemia, before treatment, November 1931. Compare with Figure 6.

Fig 6—Lymphatic pseudoleukemia, following treatment, July 1932. Compare with Figure 5

spicuousness. As evidence of the limitations of the dose may be mentioned the fact that the highest dose given to any patient (60 per cent S.E.D.—450 r—in a period of 3 weeks) was given over a year ago. This was in a case of metastatic carcinoma of the prostate. There was slight temporary palliation following the treatment. Although in this case we could see no evidence of harmful effect of this dose we have not subsequently encountered any patient for whom we felt a greater dose

(4) Especially in leukemia there is a tendency to a fall in the number of platelets in the peripheral blood and occasionally we have seen some evidence of appearance of a hemorrhagic diathesis. As is well known in connection with local irradiation of leukemic subjects, caution in dosage is obligatory.

In regard to the future of this method of therapy several possible modifications may be suggested:

(1) A modification which we have tried

in one case and hope to try in others is to use the same type of prolonged continuous irradiation for large sections of the body, shielding the rest of the body. This method would be applicable to cases like the one treated. Hodgkin's disease with extensive intrathoracic involvement, cervical and axillary lymphadenopathy, without definite involvement elsewhere, or, for example, cases of abdominal metastases of testicular teratoma, or it might be used more experimentally in selected cases to treat one-half or one part of the lesions, leaving the others untreated. With such sectional irradiation it should be possible to give larger doses with less danger of leukopenia or other undesirable effects of irradiation than would be expected were the entire body treated. We gave our patient with Hodgkin's disease 75 per cent SED (5625 r, see Fig 10).

(2) Following local irradiation, as in Hodgkin's disease, we have lately given many patients, even though no marked evidence of disease was present, a small dose (10 per cent SED) to the entire body, hoping to exercise a beneficial effect mainly on latent foci of the disease which presumably might exist in areas that had not been treated. We have been impressed by the fact that several of the patients so treated have noted a well-marked "tonic" effect soon after such treatment. Undoubtedly, the rest in bed for 4 or 5 days contributes to that effect.

(3) By removing the filter of 2 mm of copper, or by inserting in its place 1 or 2 mm of aluminum, it might be possible to secure better results in the treatment of

certain diseases manifested chiefly on the surface, such as leukemia cutis, the cutaneous lesions of Hodgkin's disease, and mycosis fungoides.

SUMMARY

(1) A new method of total irradiation is described, the essential difference from previously used methods consisting of the continuous low intensity application of the rays over periods of days to weeks with long target-skin distances.

(2) The results of this method, as tested in 118 cases, indicate that it may be a valuable adjunct to the treatment of several radiosensitive processes such as the lymphomas, leukemias, and multiple myeloma, that it may yield superior results in some cases of lymphatic leukemia, but that it may have little value in radio-resistant processes.

(3) Certain disadvantages of the method are discussed, such as the difficulty of selection of proper dosage, the failure to bring about adequate regression of some local lesions, and the development of leukopenia and thrombocytopenia in some cases.

(4) Various modifications of the method are suggested: the treatment of large sections of the body by continuous low intensity irradiation, its use in small dosage for the treatment of presumable latent foci of radiosensitive processes, following or preceding local irradiation, and the use of prolonged long distance unfiltered or lightly filtered radiation for certain cutaneous diseases.

THIS AND THAT

The rough and ready methods of our grand fathers are illustrated by the fact, related by Dr Howard Haggard, that in those days a scab was plucked from the arm of the vaccinated patient and carried in the pocket of the physician until needed. He then pared off a portion, no doubt, with his pocket knife, and in a scratch on the arm of his patient made with the point of this same useful knife, placed the paring! This was rugged simplicity," Dr Haggard remarks, but it rouses a feeling, not of admiration, but horror.

The Wayne County (Michigan) Medical Society has secured as its headquarters a fine old mansion built 30 or 40 years ago in Detroit, but hard to let or sell just now. It pays

one dollar a year rent. As the society is a nonprofit organization, the estate makes a large saving in taxes, and so can afford to give the society these advantageous terms.

A bill introduced at Albany would make it unlawful to give a false call for a physician or hospital.

All medical diplomas issued in the future by the University of Sydney, Australia, will bear not only the signatures of the graduates, but also both thumb prints, for purposes of identification. The same practice is followed in the case of all medical diplomas issued in the neighboring state of South Australia.

A Look at Pending Legislation

Our Society is concerned with the public welfare, as well as with the interests of the profession. Our solicitude is natural, therefore, when contemplated legislation affects either. We will not review all pending legislation, but rather comment on a few bills before our legislators with a view to clarifying our stand upon them.

We are wont to divide bills introduced into the Legislature into characterizing categories. We find groups of bills typifying efforts to obviate compulsory vaccination. Another group of proposed enactments would hamper and hinder medical progress and prevent the orderly course of scientific development and study, by prohibiting vivisection. Bills are introduced in the interest of technicians in various branches of medicine, chafing under the restrictions of the Medical Practice law. They are seeking the introduction of licensing bills which would give them an independent status in the State. Such legislation is unnecessary and harmful. It is based on a desire to evade the law rather than enforce it, and encourages encroachment on the legitimate domain of medicine. Additionally, we find

a group of bills whose intent is to permit irregular "cults" and "specialisms" to engage in their respective pseudomedical practices under the shadow of enacted law—all of which are attempts to weaken the Medical Practice Act.

Needless to state our opposition to all such measures is in the interest of the public welfare and the maintenance of good health among the people.

Occasionally we are confronted with proposed legislation which is both foolish and wasteful. Such is that proposed by Assemblyman Cohen. Although two thorough investigations into the workings of the Workmen's Compensation Act have been completed recently, this Assemblyman would have the State spend \$15,000 of the taxpayers' money on a third survey. And Senator Byrne proposes to set up a Bureau of Industrial Rehabilitation in the Department of Labor. Such a bureau will place the State in the practice of medicine, in direct competition with private practice, to the ruin of the latter. It is indeed hard to find grounds for either of these bills now pending in the Legislature. They should be opposed with a vigor warranted by their viciousness. Let it be known, that there will be no satisfactory solution of the medical problems associated with the Workmen's Compensation Act until the responsibility for that branch of healing is placed where it belongs—with the organized medical profession. A competent investigating committee has formulated sound and practicable recommendations. Instead of toying with proposals that are subversive of our entire system of medical practice, our legislators should be told to turn their attention to the recommendations made by the Governor's Committee of Physicians.

A bill has been introduced into the State Senate which gives the hospitals a claim upon damages awarded in negligence actions, but makes no provision for the physicians and nurses. This is a manifestly unfair attempt to protect the hospitals at the expense of their medical staffs. It is hoped that the hospital authorities will cease supporting the McNaboe-Condon bill. Hospitals, doctors, and

nurses should rally behind the bill sponsored by Assemblyman Cornaire. His bill recognizes their just rights to payment for joint services.

The O'Brien-Garnjost bill permits the establishment of a group payment plan for the hospitalization of semiprivate patients in voluntary and public institutions. Like the schemes approved in the Booth Report and adopted by the House of Delegates at its last session, this bill allows the free choice of physicians, and leaves intact the financial relations between doctor and patient. Unlike the principles advocated in the Booth Report, however, it organizes the participating groups along *industrial* lines, and places upon employers the responsibility of collecting the insurance fee. This is not the only difference. In the principles embodied in the Booth Report, the United Hospital Fund of New York City working in collaboration with the organized profession in the Metropolitan District, worked out and enunciated basic principles underlying a hospitalization payment plan. These principles were so construed, that it was a prerequisite of their adoption by the profession, that all the hospitals (private, voluntary, and public) in any given community must *all* be in the scheme, to make it applicable at all. This provision was made to guard against one hospital going into competition with another, in the same community; and the patients who were to be provided for, by the service furnished under the hospitalization payment plan, were to be within a certain specified wage-earning group, below the so-called "comfort level" of the community. Additional factors entered into the proposals which finally brought the representatives of the United Hospital Fund, and the organized profession to common ground the details of which are not germane to this discussion.

The O'Brien-Garnjost bill in its present form, lacks the desired safeguards, and it is therefore no contradiction of decisions, that the State Society which approved the recommendations of the Booth Report shall seriously consider all the implications and

possible effects of this bill entirely upon its inherent merits.

The English contributory schemes are managed by the hospitals themselves. The participants subscribe in their individual capacity, and not as a member of a particular industrial group.

The Committee on the Cost of Medical Care recommends voluntary health insurance as a precursor of the compulsory variety. The industrial organization contemplated by the O'Brien-Garnjost bill, could easily serve as an entering wedge for obligatory hospital insurance. Voluntary group provision for hospitalization is undoubtedly desirable, but the scheme adopted should permit no suspicion that it is a disguised forerunner of compulsory health insurance.

Calling Uncle Sam to the Rescue

When the farmers are in distress, they appeal to Uncle Sam and he loans them millions on farm mortgages; when home owners are hard up, Uncle Sam releases a shower of funds; banks, railroads, businesses of every description are being carried along financially by the kindly Samuel in order to avoid a general crash that would land us all in chaos. By the time the slump is over some think that our munificent uncle will have a lieu on everything in the country, and, as the government belongs to the people, our property will belong to us, only it will be by mortgage instead of by direct ownership.

It now appears, however, that, by some oversight, the doctors have been left out of this magic shower of funds distributed to all and sundry. Why isn't a doctor just as good (for a loan) as a farmer, banker, veteran, railroad president, or what you will? Millions and billions are flowing from the United States Treasury in a life-giving stream that makes the classic fertilizing floods of the Nile look like a trickle. Now is the time to get part of it.

The idea behind the suggestion, however, is founded on sound business sense. It emanates from the Lawyers Club of Los Angeles and so naturally has six "whereases" a "be it resolved" and a "be it further resolved." In spite of which

it can be boiled down to the proposition that the clients and patients of lawyers and doctors sign long-term credits for their bills and that a Federal agency discount these at a low interest rate and release the cash to the distressed men of the law and medicine. Medical bodies are asked to endorse the plan and send resolutions to their Senators and Representatives in Congress.

The soundness of the scheme appears at once when we recall that there are well-established concerns both in Los Angeles and New York, and no doubt elsewhere, which are already performing this identical service for lawyers and doctors, so that the U. S. Treasury would not be doing anything untried or experimental. The usual plan is to have the client or patient sign very much the same sort of time-payment paper as he gives for his motor car: then the finance company takes the paper and gives the lawyer or doctor the cash. Hundreds of radios, refrigerators, washing machines, and what-not are sold every day in this manner.

There is a real opportunity here, say the Los Angeles promoters of the movement, to give some quick relief without departing too far from sound financial principles.

Kentucky's Gallant Fight

A terrific set-back has been experienced by the State health authorities in Kentucky in their gallant fight with disease and death. The whole country knows the story of the county nurses who climb the stony mountain paths on horseback to bring new health and hope to the tiny cabins perched among the crags. The hardy Kentucky mountaineers, descended from the men of Daniel Boone, and of the same blood as Abraham Lincoln, are being ravaged by tuberculosis, diphtheria, hookworm, syphilis, and a score of other diseases that yield to the magic touch of modern medicine.

But in the midst of the noble efforts of doctors and nurses to clean up this bad situation, all financial aid from the U.S. Public Health Service was discontinued on June 30, last. Then the Reconstruction Finance Corporation, acting through

the Kentucky Relief Commission, extended enough aid to continue the work, but on December 1 this assistance, too, was completely and somewhat abruptly terminated, leaving approximately fifty counties either without any public health nursing services at all, or with such services so reduced as to be altogether inadequate for meeting the many problems growing out of a depression so severe as to demand a nationwide set-up for relief. The Kentucky State Board of Health, which reports these facts, says that "no more distressing circumstance has ever developed in connection with public health work in the state; it means a set-back for county health work which many years will be required fully to counteract." Federal aid had been given for seven years; the work had come to rely and depend on it, and the loss of it now "creates a situation as embarrassing as it is deplorable."

How deplorable the conditions are in the blue-grass State is revealed in the stories of the devoted public-health workers. They seem almost past belief in our great rich America. Take McLean County. Thirty per cent of the families are receiving relief. Underweight children in the schools have increased 46 per cent since 1929. The parents of the families on relief have "no money, no jobs, no visible means of support, and insufficient food. Many children and parents, too, are half-fed, almost naked. Many children have rickets, some grown people have pellagra."

Some of the mountain schools visited by the public-health workers seem to belong to the dark ages. In Leslie County, in eastern Kentucky, among the mountains, many of the schools are from 20 to 30 miles from the county seat and can be reached only on horseback. The school buildings are deplorably primitive, sanitary conditions are terrible, the roofs leak, the windows are "shot out," the desks and benches are rough boards, and the stove is the only "brought on" article in the building. Often, in fact, there is no stove. Not infrequently the health worker finds the school closed and the teacher gone fishing or squirrel hunting. The effect of unsanitary conditions on the children's health

need not be explained to the reader of these papers. Few of the schools in Leslie County have sanitary toilet facilities. Most of them have none at all. As a consequence, practically every school child has hook-worms or other intestinal worms. Sanitation "is urgently needed over the entire county." Yet this is the time when the withdrawal of federal aid brings the work to a halt.

Fathers and mothers in the back districts are often cold or hostile to the new-fangled health ideas. It is the children who break down all opposition. One woman who came with her twins to a health conference in Powell County said; "I don't bring my twins; they bring me." Every child is eager for the "blue ribbon," awarded to those who have had all defects corrected, so they give their parents no rest till their eyes and teeth are attended to and they are immunized against small-pox, diphtheria, etc. The "blue ribbon" program is given each May Day. Many parents have said to the county health staff: "I am broke now, and it's your fault; for my children needed their teeth corrected to get blue ribbons. They kept worrying me until I had to have it done." The local dentists say the health department is working them to death. Families are also learning what Grade A milk is, and many undernourished children have gained 10 to 12 lbs in the past year.

Ignorant midwives, or "grannies," have been unwittingly responsible for disease and death among mothers and children, but the glad news of better maternity care is spreading like a new gospel through the hills. In the beginning the nurse had to seek out expectant mothers and ask them to come to the clinic, but the word has passed from cabin to cabin and from valley to valley until last year fully half the women who came to the prenatal clinics in Anderson County were previously unknown to the health department. One midwife, 74 years old, walked four miles to the Edmondson County clinic, bringing four "prenatals." The infant mortality among babies whose mothers did not attend the clinics is much higher, and the news of this fact soon goes around.

Sometimes a mother who cannot come borrows the book of instructions from a mother who came. She proudly says she raised her baby "by the book," and such babies are always up to normal standards in every respect, we are assured. "Healthy Baby Contests" rouse enormous interest. The judges are physicians from outside the county, perhaps as a safety-first precaution.

The difficulties are formidable. No roads exist in some sections, and many towns in Rowan County are isolated the year round. Others are isolated from September to May. It seems that in "this semi-mountainous district, nine-tenths of the people speak a language peculiar to parts of Kentucky, Virginia, and Tennessee. Many social lags, old customs, peculiar religious beliefs and health cults are to be found." We are told that one boy who had to be "'beaten' every day and then 'didn't seem to larn nuthin,' was found to have such poor vision that he could not see one's five fingers at a distance of five feet. The health department is attempting to correct such conditions, but, unfortunately, many of the parents are poor and ignorant and insist that they can 'whup' enough to make good citizens of the worst handicapped."

One day the health department of Lincoln County was asked to look in on a school to "see about a breaking out" which the children had. The worker found that 25 per cent of the school were at home ill and the remaining 75 per cent had either previously had scarlet fever or were undergoing the various stages while still attending school. The community received such full instructions on the subject that such a situation cannot happen again. Meantime, diphtheria had also appeared, and 1,263 children received immunization.

And so the story could go on and on, but enough has been told to show, perhaps, that health work is fully as important as some other things the public money is being poured into. It is to be hoped that we may hear soon that Kentucky's health workers are again on their beneficent rounds.

Doctors' Telephone Refunds

Excellent results have followed the brief paragraph in our issue of February 1 informing our readers that doctors are entitled to the lower residential rate on their telephones when their offices are located in their residences. Since the item appeared, our business management has received more than 50 telephone calls, letters and other inquiries in regard to it. We have secured a nine-year credit refund for one doctor, a seven-year credit refund for another, not to mention smaller adjustments. The ruling of the New York State Public Service Commission is that the residential rate, rather than the higher business rate, shall apply on the telephone of a physician, surgeon, osteopath, chiropodist, optometrist, chiropractor, Christian science practitioner, veterinary surgeon, nurse or physiotherapist, when the office is in the subscriber's residence. We feel that it is a privilege to perform services of this nature for the physicians of the State, and we shall be more than pleased to aid in any other problems where our friends may wish advice or assistance.

The Race of Stork and Reaper

One of the classic stories handed down from generation to generation in the newspaper offices has it that a young headline writer, editing a report on birth and death rates, wrote the caption: "Stork Shades Grim Reaper." What would he write over the annual report of life, death, and disease in 1933 for New York State, bristling as it is with superlatives in every direction you may look?

The poor stork presents a sorry appearance, with the birth rate the lowest ever recorded. The number of births last year was nearly 13,000 less than in 1932. The old saying that births increase after a great war is shot to pieces. The state birth rate in 1914 was 24.6 per 1,000 population, the highest ever known. Last year it was 14.0, the lowest ever recorded. In six years it has dropped more than 25 per cent. The windows of the bird stores are filled with various preparations guaranteed to give the birds more pep and vigor—some kind-

hearted person might well send a box of it to the winged messenger whose wings appear to be growing a bit weary.

To make up in some part for the falling birth rate, we learn that the rate of infant mortality, 54 deaths under one year per 1,000 live births, was practically equal to the minimum recorded in 1932.

But if our old friend the stork is lagging in his task, our old enemy with his sickle keen is also slowing up. The death rate last year dropped to the lowest point ever known in the State. The editor of Health News, organ of the State Department of Health, remarks that the significance of this fact is likely to be misunderstood or misinterpreted. Some superficial, perhaps rather callous, observers see here a beneficial effect of economic deprivation. This, of course, is not true, he says. Surveys are now being made to discover the cause and we shall know the real reason when the reports are in.

When we come to examine the mortality reports in more detail we find some encouraging features that may well cheer the profession that is waging a never-ending battle with death and disease. The pneumonia death rate, 91.2 per 100,000 population, has never been lower, and, in fact, rates below 100 were recorded only twice before, in 1921 and in 1932. The death rate from diphtheria, 1.1, was about half the previous minimum of 2.1 registered in 1932. The rate from whooping cough, 2.2, was never lower.

Turning to the darker side of the picture, the Health News tells us that the disquieting rise in maternal mortality, first noted in 1930, is still going up, and the 1933 rate of 60 deaths per 10,000 live births was the highest in 15 years. The increase over 1932, it seems, was due entirely to a rise in the mortality from puerperal sepsis, a fact which should carry its lesson to those who are working earnestly on this vital problem.

The death rate from cancer, 127.5, also rose to a new maximum, and the rate from diabetes, 30.3, set a new high.

The State health report is like the battle bulletins issued during the great war, telling of a mile gained here, a mile lost

there, positions taken, lost and stormed again, thousands killed, wounded, or captured from the enemy. And meantime the war goes on, in the little hamlet in the hills, in the smoking factory town, in the homes of the rich and the tenements of the poor, up and down the city streets. Already the records of 1933 are months behind us, and we are making the figures for 1934. One of the great battles of the Crimean War was called "the soldiers' battle" because the men took the conflict into their own hands and fought it to a victory. That is the kind of battle the physicians are waging. It is a hand-to-hand fight, and they are capturing more and more enemy territory every year and every day.

The cost of public medical service in New York City, not counting the free service of private institutions 'has in the last twenty or thirty years doubled and trebled itself' said ex Mayor McKee in his address at the Academy of Medicine. "Slowly but surely," he declared the government is assuming more and more the work of the private physician."

A cheerful view of the increase of deaths from heart disease in older age brackets is taken by Dr. Donale B. Armstrong, third vice president of the Metropolitan Life Insurance Company. There is something to be said' he observes in *American Medicine* 'from the point of view of man's comfort, in favor of gradual increase of sudden cardiac deaths on the gold course and elsewhere from coronary disease, to the extent to which this method of terminating life eliminates long periods of decline and invalidism. Looking at the problem from this angle, may we not even be justified in referring to that type of heart disease in the terms which Osler applied to pneumonia, namely, 'A friend of the aged!'"

Doctors distracted by worries in these troublous times may welcome the advice of a fellow-practitioner in Mississippi, who gives his prescription in a letter to his medical journal. "If you want to forget all your troubles" he writes get up a jolly good crowd of men a good pack of deer dogs and go hunting, nothing so exciting as for a big buck to almost run over you. Mims Mitchell, our efficient funeral director and myself have just gotten off of a fine hunt. Bagged four deer."

A connection between the Ford car and the reduction of mortality of gastric cancer is found by the alert editor of the *New England Journal of Medicine*. Early x ray examinations are essential he remarks and 'everyone knows the reason why a gastro intestinal x ray is avoided. It is because one wishes to save the patient money. And the remedy? Increase the number of x rays reduce the cost and ask the originator of the Ford car how it can be done."

Correspondence

Anonymous letters will not be noticed. All communications must carry full name and address of the writer but these are omitted on request.

To the Editor

From among the many excellent things in the last issue of the JOURNAL I want to pick out your editorial 'Making the Public too Health conscious' and say 'Allah be praised for it'. For many a long day I have ranted in my feeble way along these same lines and now you come along and put something in print so much better than I could say it—it fills me with joy.

Damn most of this health education. I do not remember seeing a single patient who has come sooner because of this education but I have seen innumerable women who are going to their graves obsessed with the idea that they have cancer and the Lord Almighty could not make them believe otherwise.

All of the editorials are excellent but the one mentioned is outstanding. I wish that you would put it out as a pamphlet so that I could distribute it to a lot of moronic damn fools.

WARREN L. DUFFIELD

To the Editor

Page 127 February 1st Review by John F. Jennings on what everyone should know about cancer.

My regards and admiration to Dr. Jennings—honest and fearless.

JOHN F. WHITE, M.D.

To the Editor

I read to-day your editorial on the subject of Sterilization. There was in Sunday's New York Times in the Magazine Section by Sanford Bates a concise well stated article on The Prison. I saw also in the Times one day last week resolutions passed by the Women of Savannah, Georgia and handed to the Mayor the Board of Aldermen of that City commending the practice of sterilization upon the unfit.

Kindly advise me regarding what 27 states as you state now legally permit this surgical procedure.

In addition to its practice upon the unfit I am interested concerning its employment as a crime deterrent, and want to be informed where I can find information leading in this direction. What can you tell me? Is anything being done abroad in combating crime by this method?

DR. HENRY H. COVELL

[Twenty six states have sterilization laws North Carolina was the twenty seventh but its law has been declared unconstitutional by the State Supreme Court. The twenty six are Maine New Hampshire Vermont Connecticut Delaware Virginia West Virginia Alabama Mississippi Michigan Indiana Wisconsin Minnesota Iowa North Dakota South Dakota Nebraska Kansas Oklahoma Montana Idaho Utah, Arizona, Washington Oregon and California.]

Legislative Bureau

Bulletin No. 7, February 24, 1934

ACTION ON BILLS

SENATE BILL INT. No. 385—Wicks, unemployment relief funds, passed by the Senate.

SENATE BILL INT. No. 297—D. T. O'Brien—Assembly Bill Int. No. 324—Garnjost, hospital service plans exempted, passed Senate and reported out in the Assembly.

SENATE BILL INT. No. 568—Esquirol—Assembly Bill Int. No. 695—V. C. Lewis, tuberculosis hospitals control, amended by requiring superintendent of hospital to be "licensed or eligible for licensure in New York State."

SENATE BILL INT. No. 566—Berg, professions entrance requirements, third reading.

Assembly Bill Int. No. 353—Hamerman, health law domestic servants amended to exempt persons with infectious diseases while in quiescent state.

HEARINGS

February 27—All bills in Labor and Industry before the joint committee.

February 28—Breen Antivivisection at one p.m.

March 6—Two Pharmacy bills, Assembly Int. No. 415, Assembly Int. No. 417, Dunkel.

March 13, 14—Two per cent sales tax bill, Fearon.

On Tuesday, February 20, the Assembly Committee on Education heard representatives of the Osteopathic Society, the Assistant Commissioner of Higher Education of the Department of Education and Dr. Lawrence on the merits of the osteopathy bill. The committee has not taken action on the bill but we believe the osteopaths did not strengthen their position of last year by any new arguments. It was stated that the Regents had voted not to support the bill this year.

NEW BILLS INTRODUCED

SENATE INT. No. 758—Wicks—Assembly Int. No. 1012—Bentley, offers amendment to the General Municipal Law, by authorizing supervisors of county without purchasing agent or auditing commission to make appropriation for maintenance expenses of public general hospital. Referred to Cities Committee.

Comment.—A copy of this bill will be mailed early next week. It needs careful study, for one part of it seems to give the financial control to the board of supervisors in such counties where no purchasing agent or auditing commission exists. There is a question in our mind as to whether it is wise to give the board of supervisors such control or whether it should not rather rest with the board of managers.

SENATE INT. No. 890—Buckley, would amend the Civil Practice Act by providing for the appointment by the court of one or more expert witnesses whenever expert evidence is required. Referred to the Codes Committee.

SENATE INT. No. 903—Lord—Assembly Int. No. 1110—Deyo, adds new section to the Public Health Law, prohibiting sanitary regulations and sanitary code amendments limiting sale of milk or cream obtained from cows suffering from Bang abortion disease until provision is made for disposing of such cattle and for payment of indemnity. Referred to the Health Committee.

ASSEMBLY INT. No. 1143—Murphy, offers the following amendment to the Civil Practice Act: for preference of action brought by person injured in course of employment and entitled to workmen's compensation and who elects to sue third party. Referred to Codes Committee.

ASSEMBLY INT. No. 1144—Murphy, adds new section to Workmen's Compensation Law, for procuring special medical services for claimants with controverted claims, who are unable because of poverty to secure necessary examinations or other medical evidence. Referred to Labor Committee.

ASSEMBLY INT. No. 1145—Murphy, adds new subdivision to section 15, Workmen's Compensation Law, for reopening of claim where claimant requires further medical treatment or his condition has changed or schedule loss has increased over allowed percentage. Referred to Labor Committee.

To those of you who are not chairmen of County Society Legislative Committees, you will find a copy of the white book inclosed. We are sorry we are so late in supplying this information but it is due to the fact that both chambers of the Legislature were unusually late this year in effecting a permanent organization. Again let us call your attention to the necessity of filing with your legislators your approval or disapproval of the following bills:

APPROVED

SENATE INT. No. 66; Assembly Int. No. 296: Hospital lien bill, including physicians.

ASSEMBLY INT. No. 289: Free choice of physician.

DISAPPROVED

SENATE INT. No. 45; Assembly Int. Nos. 141, 169, 570, 728: Occupational disease bills.

SENATE INT. No. 235; Assembly Int. No. 419: Labor clinics.

SENATE INT. No. 336: Antivaccination bill.

SENATE INT. No. 450; Assembly Int. No. 715: Osteopathy bill.

SENATE INT. No. 505: Physiotherapy bill.

ASSEMBLY INT. No. 364: Antivivisection bill.

Bulletin No. 8, March 2, 1934

ACTION ON BILLS

SENATE INT. No. 297—O'Brien, hospital service plans exempted, has been substituted in the

Assembly for Assembly Int No 324—Garnjost, and advanced to third reading, but referred to committee for amendment

SENATE INT. No 566—Burg, entrance regulations to professions, has passed the Senate and been referred to the Education Committee in the Assembly

ASSEMBLY INT No 215—F M Smith, milk fat tests, reported out in the Assembly

ASSEMBLY INT No 1012—Bentley, amending the Municipal Law with regard to county hospitals, passed the Assembly and referred to Committee on Cities in the Senate

HEARINGS

March 6 at 2 P M—Pharmacy bills, Assembly Int No 415, Assembly Int. No 417—Dunkel

March 13 to 14, two per cent sales tax bill—Pearson Wadsworth

On Tuesday, February 27, there was a hearing before the Joint Committees on Labor and Industry on all bills that have been referred to those two committees. In previous years this hearing has drawn large crowds and stimulated very exciting debates, but this year's hearing was an exceptional one in these two respects, first, there weren't so many people present and, second, only two bills occasioned much debate. They are the bill limiting the hours of work of state employees to eight and another regulating the conduct of public employment agencies. Of course, many of the bills that were scheduled for the hearing have been debated in previous years, and at the suggestion of the secretary of Federated Labor, we all agreed to file with the two committees briefs conveying our points of view on those bills that we did not agree upon at the time of the hearing. This probably will prove a more satisfactory way for the committees to know how our various organizations feel toward certain bills than to have them discussed, because so many people have very poor terminal facilities when they get upon their feet and others find it very difficult to say what they have in their minds and muddle it up considerably. Prior to the hearing we had filed with every member of the two committees our reactions to the bills that were before them, and we have begun to discuss with members of the committees those bills that are most debatable.

On Wednesday, the 28th, we had the annual hearing on the antivivisection bill. In opposition to the bill Dr Morton introduced the following: Drs Peyton Rouse, C P Rhoads, and Florence R Sabin, of Rockefeller Institute, James W Jobling, Professor of Pathology at Columbia University, John Wyckoff, Dean of Bellevue Medical School, Frederic C Sondern, representing the Academy of Medicine, George Whipple, Dean of the University of Rochester Medical School, G Canby Robinson, Dean of Cornell Medical School, Barbara B Stimson, Assistant Surgeon at Presbyterian Hospital, Walter L. Matlack, of the State Institute for the Study of Malignant Disease also Dr A B Wadsworth of the State Laboratory and Dr Harold Rypins of the State Department of Education. Those appearing for the bill were some of those who have appeared regularly. Dr Murphy, who is now an Assemblyman, cross-examined most of those who spoke in opposition to the bill and spoke in favor of it himself,

pleading with the committee to report the bill out so that a vote might be taken on it on the floor. (Dr) Benedict Lust, who said he conducts a school on naturopathy in New York City, spoke in favor of the bill. The proponents of the bill gave no more specific reason for the amendment than was given in previous years and the bill will likely receive the same fate.

NEW BILLS INTRODUCED

SENATE INT No 926—Feld would amend the General Corporation Law by prohibiting a corporation from using the word Doctor or the abbreviation Dr as a part of its name. Referred to the Judiciary Committee.

There is a great need for this amendment. It originated with the Department of Education and we are sure that you are ready to support it.

SENATE INT No 949—Byrne, appropriates \$20,000 to increase supervisory services in State Education Department to develop more satisfactory preventive and corrective physical education and recreation programs for children and adults. Referred to the Finance Committee.

SENATE INT No 954—Esquirol, Assembly Int. No 1288—V C Lewis amends the Public Health Law by empowering Public Health Council to prescribe qualifications for appointment after December 31, 1934, of dairy and milk inspectors and operators of public sewage treatment plants and public water treatment and purification plants. Referred to the Health Committee.

ASSEMBLY INT No 1304—Stewart, amends the Education Law for supervision of clinical laboratories by persons licensed to practice medicine. Referred to the Education Committee.

This bill adds two new sections to the section on definitions of the Medical Practice Act, namely, a definition of 'laboratory' and of 'clinical laboratory' and then adds to the section on penalties a section which would make one who is not a licensed practitioner of medicine guilty of a misdemeanor if he conducted, directed, supervised, or controlled the work or reports of a clinical laboratory, and a clinical laboratory is defined as a building or room where tests are made on individual persons, their secretions, excretions, blood and tissues to aid in the diagnosis, prognosis, or treatment of the individual's physical or mental state or states.

ASSEMBLY INT No 1357—Streit, adds new section to the Penal Law making it a felony for any physician wilfully and unnecessarily to change characteristic finger markings of a person's fingers or thumb by operation or otherwise. Referred to the Codes Committee.

We are working hard to advance the Byrne Cornaire hospital lien bill. We have asked all of the general hospitals in the State to submit us a statement of the amount of money they failed to collect for services rendered cases of personal injury in either the month of June or July. Probably less than 50 per cent of the hospitals have replied as yet, but some of these show amazing losses. We are certain that the members of the Judiciary Committees will be impressed by the great sacrifice that hospitals, physicians and nurses are called upon to make. We are pressing the point with the committees

that compensation for these services is not necessarily a responsibility of the individual who was injured, but rather of the insurance company that carried his insurance, and following that lead we accuse the insurance companies of being highly unfair in opposing the advancement of the bill.

The hospital, physician, and nurse called upon to take care of the injured individual have no opportunity to seek instruction from the insurance company, but it would not be asking too much to expect the insurance company when it is notified of the accident, to communicate with the hospital, physician, and nurse, authorizing their services in the care of this patient, who in his present condition is an immediate liability to them; on the contrary, insurance companies usually say nothing but wait for the patient to leave the hospital and then attempt a settlement with him. The argument which they bring forth at the present time is that it would be necessary for them to secure releases from so many physicians and nurses that it would make a settlement almost impossible. If, however, the insurance companies were to take an interest in the patient immediately that they receive the first notice of his injury, there would be no physicians or nurses on the case that the insurance companies would not know about, and when the time for settling the case came, releases could be gotten as promptly from them as from the hospital. It should be remembered, too, that certain insurance companies issue policies at the present time making special provisions of a specified amount to be paid the hospital for emergency care it may render; also a stated amount to be paid the surgeon if surgical services are needed. So far as our information goes, it is an exceedingly rare occasion when an insurance company notifies the hospital that an injured man carries a policy with these conditions; on the contrary, such injured persons are allowed to leave the hospital without making any payment whatever, regardless of the fact that the policy which the patient carried specifically made those provisions. The injured person cannot be held entirely responsible for this because many men do not know the full provisions of their policies and when they are taken to the hospital may or may not be conscious; at any rate, they are most likely not to be in such condition as to be able to take care of their affairs and that is the reason they carry the insurance policies.

We hope that your enthusiasm will mount with ours in supporting this bill. Can you not ask your hospitals to have the proper person interviewed by your local newspapers upon the matter? Also call upon your legislators who are home over the week-end and press the matter with them. We have had some very encouraging interviews with legislators. Several of the leaders have told us that they are sympathetic to the bill and will vote for it. The strong opponents to the bill are the insurance carriers and we believe that they can only op-

pose it so long as the public remains ignorant of the true state of affairs.

It is tremendously important that you immediately give this bill and your support of it as much publicity as you can.

Special Bulletin

March 7, 1934.

Yesterday we had a hearing before the Judiciary Committee in the Assembly on our hospital lien bill—Assembly Int. No. 296—Cornaire. We are quite satisfied with the manner in which the committee received us and the discussion of the bill which ensued. We are not certain that we have convinced a majority of the committee as to the merits of the bill, but certainly we have more friends than we did prior to the hearing. We have also had an invitation from the Senate Committee to discuss the matter with them next Tuesday.

Please continue your solicitations with your legislators and especially with members of the Assembly and Senate Judiciary Committees. For your benefit the personnel of the two committees follows:

Senate Committee on Judiciary

William T. Byrne	Julius S. Berg
Philip M. Kleinfeld	Perley A. Pitcher
Elmer F. Quinn	Cosmo A. Cilano
John L. Buckley	Walter W. Westall
Marcellus H. Evans	Seabury C. Mastick
John J. McNaboe	Frederick J. Slater
Joseph D. Nunan, Jr.	

Assembly Committee on Judiciary

Horace M. Stone	Martin W. Deyo
Jasper W. Cornaire	Leonard W. Hall
Harry A. Reoux	William E. Morris
Rainey S. Taylor	William C. McCreery
Ralph A. Gamble	Millard E. Theodore
Harry F. Dunkel	Albert M. Cohen
Herbert Brownell, Jr.	Patrick H. Sullivan
	Carl Pack

You can write to them in Albany at any time, but we recommend that you see them personally, if possible, while they are home over the week-end.

Some of the arguments which seemed to have the greatest weight with the committee yesterday are: (1) Great sums of money are lost annually by hospitals in caring for persons injured in automobile accidents. In some hospitals this loss is a large share of the deficit. Some of these patients recover from insurance companies for their injury and should be obliged to pay the hospital, physicians and nurses; (2) The community in which the hospital is located must, in its financial support of the hospital, make good this loss. The physician and nurse must bear their own loss; (3) That the tendency on the part of injured persons to neglect their responsibility to the hospital, physicians and nurses is fast becoming a racket; (4) That a lien of this character would tend to interfere with prompt settlement of cases by insurance companies. It was admitted that very likely it would be more difficult to make a settlement and that certain injured persons for whom the amount of the settlement might not be more than enough to cover the medical

expenses, would lose interest in effecting a settlement, but this argument, naturally, sprung from the insurance companies and we should attack it as vigorously as we can. The insurance companies are not contributing any extra time or service without remuneration. If it takes long to settle the case, they will eventually see that that expense will be covered by the premium.

The information which the hospitals sent us regarding their losses, which would be affected by this bill, was very valuable and convincing. We suggest that the hospitals send the same information to their legislators and especially to the members of these two committees. There is a growing opinion manifest among the legislators that we have a real serious problem which needs correction and it is highly important, therefore, that we build to this growing sentiment.

Again we suggest that the public press be used. The more we stimulate public interest in this question, the more certain we are of accomplishing our wish. Therefore, **COMMUNICATE WITH YOUR LEGISLATORS AT ONCE, DO NOT POSTPONE THE MATTER.** Send a second or a third communication. The first may have been lost or the legislator may be in a more receptive mood when he receives a second or third.

Remember the number of the bill. Senate Int. No. 66—Byrne, Assembly Int. No. 296—Cornaire.

WE HAVE A SPLENDID CHANCE OF PASSING THE BILL IF WE ALL WORK TOGETHER.

Announcement

A Survey on the Incidence of Cretinism in the United States

The JOURNAL is glad to publish the following letter and to recommend to the members of the Medical Society of the State of New

York that they assist Dr. Jackson in his valuable effort. The JOURNAL has full knowledge from authoritative sources of the high standing of all those connected with the Jackson Clinic.

III. JACKSON CLINIC

16 South Henry St.
Madison, Wisconsin

Feb 12, 1934

New York State Journal of Medicine,
2 East 103rd Street,
New York, N. Y.

Dear Sirs:

I am making a survey on the incidence of cretinism in the United States and would greatly appreciate it if you would insert a notice in your JOURNAL to this effect and ask any of your readers who might have records of such cases to communicate with me. I am enclosing a form which contains the information desired.

No one has ever attempted to make a survey of this kind and it will only be through the cooperation of the medical journals and the profession that it will be possible to make such a survey. I will be especially interested to receive any photographs of these cases. I am asking that the names and addresses to be given in order to eliminate the duplication of cases. When these data are compiled I expect to turn them over to the American Medical Association where they may be filed for further reference and study.

Sincerely yours,

ARNOLD S. JACKSON, M.D.

SERVICE AND SUCCESS

That the ability to pass the exams in medical school with flying colors is not everything was well illustrated by Dr. John A. Rockwell in his address at the graduating exercises of the internes of the Massachusetts Memorial Hospitals. In his class at the medical school, he recalled, was one candidate whose marks were so close to the line that several faculty conferences were held before making their final decision in his case. He was poor, he had had no collegiate or premedical training, he had borrowed more money to become married in his senior year, he had few qualifications save the spirit of service and this alone influenced the faculty to grant him his degree. He was always the last student to leave the dispensary clinics and would at

tend any call in the district no matter how tired or how late the hour. This classmate settled in a small town in Maine without even having had hospital internship. When he arrived on a bicycle ready for service, there were four other physicians in this community to whom he was a laughing stock and a joke. At the end of ten years he had superseded them all and was a highly successful and useful physician having won the trust and confidence of the people to an unusual degree.

A bill at Albany would forbid the employment of nurses more than eight hours a day in hospitals supported wholly or partly by public funds.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

EVIDENCE—TESTS TO DETERMINE THE TRUTH OR FALSITY OF TESTIMONY

In recent years considerable publicity has been given in the public press to the development of certain tests devised to aid in the determination of the truth or falsity of statements made by a person charged with crime. Of these tests the one which has been given most prominence is the systolic blood pressure test, commonly called the "lie-detector method." The use of this method has been on at least two occasions the subject of judicial ruling by the Appellate Courts of other states.

The use of the lie-detector method requires an apparatus which records continuously the blood pressure of the subject. A roll of paper is used upon which are automatically plotted in curves showing the variations in blood pressure. In ordinary use, the subject is seated comfortably in front of the apparatus with it so arranged that any changes in his pulse or blood pressure will deflect the instrument accordingly. He is asked a series of questions, a number of which are entirely irrelevant and others of which bear directly upon his relation to the crime of which he is a suspect.

Experience has demonstrated that in some instances this machine has served to break down a lying subject and causes him voluntarily to confess his crime. It would seem, however, in these cases that the value of the machine is largely psychological. The subject probably really believes that the machine can accurately determine whether his statements are true or false. In cases, however, where no voluntary confession is obtained, it is difficult to see any probative value in such a test. Obviously, an innocent person might react to the test so that guilt could be shown, while a guilty man might well maintain an attitude under questioning so that nothing could be determined against him by such a test.

Several years ago, in the District of Columbia, the results of such a test were sought to be used as evidence upon a trial. A defendant being tried for murder offered by his attorney the testimony of an expert witness to testify to the result of a systolic blood pressure deception test that

had been made upon him. The trial judge refused to permit the testimony to go into the record. An offer was then made that the witness should make such a test in the presence of the jury, which was also denied. The man was convicted of murder in the second degree. An appeal was taken and the rulings affirmed. The Appellate Court in its opinion discussed the deception test as follows:

"It is asserted that blood pressure is influenced by change in the emotions of the witness and that the systolic blood pressure rises are brought about by nervous impulses sent to the sympathetic branch of the autonomic nervous system. Scientific experiments, it is claimed, have demonstrated that fear, rage, and pain always produce a rise of systolic blood pressure, and that conscious deception or falsehood, concealment of facts, or guilt of crime, accompanied by fear of detection when the person is under examination, raises the systolic blood pressure in a curve which corresponds exactly to the struggle going on in the subject's mind, between fear and attempted control of that fear, as the examination touches the vital points in respect of which he is attempting to deceive the examiner.

"In other words, the theory seems to be that truth is spontaneous, and comes without conscious effort, while the utterance of a falsehood requires a conscious effort, which is reflected in blood pressure. The rise thus produced is easily detected and distinguished from the rise produced by mere fear of the examination itself. In the former instance the pressure rises higher than in the latter, and is more pronounced as the examination proceeds, while in the latter case, if the subject is telling the truth, the pressure registers highest at the beginning of the examination, and gradually diminishes as the examination proceeds."

The Court determined that the reliability of the test had not been satisfactorily established to permit its use in evidence, and stated:

"Just when a scientific principle or dis-

covery crosses the line between experimental and demonstrable stages is difficult to define. Somewhere in this twilight zone the evidential force of the principle must be recognized, and while courts will go a long way in admitting expert testimony deduced from a well recognized scientific principle or discovery, the thing from which the deduction is made must be sufficiently established to have gained general acceptance in the particular field in which it belongs.

'We think the systolic blood pressure deception test has not yet gained such standing and scientific recognition among physiological and psychological authorities as would justify the courts in admitting expert testimony deduced from the discovery, developments and experiments thus far made.'

Subsequently to the said decision the precise question again came up in court very recently in the State of Wisconsin. A defendant was charged with bank robbery. His attorney during the trial offered to put on the witness stand a certain professor, who was connected with the so-called Crime Detection Laboratory of a well known university. The purpose of his testimony was to show that he had made a systolic blood pressure test upon the defendant with a "lie detector" and that it had established the truth of his claimed alibi that he was not in the same city as the robbery on the day it took place.

The defendant was convicted and on appeal sought a reversal on the grounds of the exclusion of the said evidence. It was urged on appeal that the systolic blood pressure test had been used in over ten thousand cases, and that 75 per cent of those upon whom two such tests had been made had confessed their guilt, and that consequently the method was now of sufficient scientific accuracy to be accepted as definite evidence of guilt or innocence.

The Court on Appeal, however, refused to disturb the ruling of the trial Court. It concluded that the deception test was still too much in the experimental stage to be used as proof in a court of law. For this conclusion it cited the authority of Dean Wigmore probably the foremost authority on evidence in this country, to the effect that no safe generalizations as to the probative value of the tests could yet be made. In its opinion the Court said:

"While it may have some utility at pre-

sent, and may ultimately be of great value in the administration of justice, it must not be overlooked that a too hasty acceptance of it during this stage of its development may bring complications and abuses that will overbalance whatever utility it may be assumed to have. The present necessity for elaborate exposition of its theory, and demonstration of its practical working, in order to convince the jury of its probative tendencies, together with the possibility of attacks upon the soundness of its underlying theory and its practical usefulness, may easily result in a trial of the lie detector rather than the issues in the cause. If the defendant in a criminal case is to be permitted to have tests taken outside of court and then to produce expert testimony as to the results of the tests when these are favorable to him, without the necessity of taking the stand or submitting to tests by the prosecution, the way would be open to abuses that would not promote the cause of justice."

Both of these decisions are undoubtedly correct. It should be noted, however, that neither court denounced the method but rather expressed a hope that further research and experimentation might establish more certain results in the detection of crime.

It is interesting to note that the courts have encountered other types of lie detecting devices, the proponents of which have failed to show that their methods have been other than fakes or quackery. One such instance came up in Missouri a few years ago in the trial of a rape case. The defense sought to put in evidence the deposition of a doctor to the effect that he had administered to the defendant what he called a "truth-telling serum," and that while under its influence the defendant had denied his guilt. In that case the point was taken up on appeal, and the Appellate Court, quite properly, we believe, regarded such testimony with suspicion, and affirmed the conviction, saying in its opinion:

'Testimony of this character—barring the fact that it cannot be otherwise classified than as a self serving declaration—is, in the present state of human knowledge, unworthy of serious consideration. We are not told from what well this serum is drawn or in what alembic its alleged truth-compelling powers are distilled. Its origin is as nebulous as its effect is uncertain. A belief in its potency, if it has any existence,

is confined to the modern Cagliostro, who still, as Balsamo did of old, cozen the credulous for a *quid pro quo*, by inducing them to believe in the magic powers of philters, potions, and cures by faith. The trial court, therefore, whether it assigned a reason for its action or not, ruled correctly in excluding this clap-trap from the consideration of the jury."

Death Following Extraction of Teeth

A physician engaged in general practice who had had considerable experience in administering anesthesia was called to the office of a dentist to give an anesthetic to a patient upon whom certain extractions were to be made. She was a young woman about 21 years of age in apparent good health. The doctor examined her very carefully, testing her lungs by stethoscope and percussion, testing her heart, examining her urine, and looking in her mouth for loose teeth or foreign bodies. He decided that she was a fit subject for a general anesthesia. Thereupon he placed her in the dentist's chair and administered nitrous oxide-oxygen anesthesia. The dentist proceeded to extract three lower incisors and one cuspid and inserted a single suture in the gums, which required not more than ten minutes. About five minutes after the completion of the dental work the patient regained consciousness and was permitted to lie down on a bed in the office. The physician remained in attendance upon her, and about half an hour later he observed that the patient's lips and face became pale and her pulse very rapid and weak. He gave her a hypodermic of digifolin and a few minutes later one of camphor and oil, followed by a hypodermic of adrenalin. She did not respond to all efforts made to resuscitate her and passed away, about forty minutes after she had been placed on the bed.

The Medical Examiner was notified and he examined the body and made out the death certificate, but no autopsy was performed.

An administrator was appointed for the girl, who instituted an action against the physician and the dentist, the former being represented by the counsel for your Society. The complaint charged both defendants with having been negligent in the administration of the anesthesia and

in the extraction of the teeth, and claimed that their negligence was directly responsible for the patient's death.

The case came on for trial in due course before a judge and jury and at the close of the testimony, motions were made on behalf of the defendants to dismiss the action on the grounds that no proper proof had been put in to connect up the death with any negligent or improper act of either the dentist or physician.

The trial judge granted the said motions and judgment was entered dismissing the plaintiff's complaint.

Treatment of Warts

A young lady consulted a physician who specialized in surgery and neurology with respect to the treatment and removal of certain warts on the back of her left hand. The doctor tried to treat the warts by application of a solution of nitric acid. A few days later she returned and he found that the attempted treatment was ineffectual. He then suggested undertaking to remove them by the fulguration method and the patient consented. Placing her in a chair he proceeded to sear over three large warts with an electric needle. Several days later she returned, and the warts so treated were gone, but she complained of a slight swelling of the hand and wrist. He advised cold applications of boric acid solution. He saw her several times after that, and when he last saw her at the end of two weeks the swelling was gone and he did not find any indication for surgical treatment.

The patient later brought a malpractice suit against the physician, making the claim that he had used defective instruments and improper methods in treating her. She claimed that he was responsible for the swelling that developed, and she further claimed that due to negligence scars had developed at the site of the warts. A physical examination was made of her by another doctor, at the request of the defendant's attorney, and he found that she had two small white scars that were scarcely noticeable at the former location of the warts. Repeated attempts were made by the plaintiff's attorney to persuade the defendant's attorney to make an offer to settle the case. No such offer was made in behalf of the doctor, and on the eve of trial the plaintiff voluntarily discontinued the action.

SOME PRACTICAL PROBLEMS IN THE HANDLING OF PERIPHERAL ARTERIAL DISEASE

W. J. MERLE SCOTT, M.D.

From the Department of Surgery, The University of Rochester School of Medicine and Dentistry, Rochester, N. Y.

The adage "familiarity breeds contempt" is nowhere more true than in clinical problems. The commonplace in medical practice is apt to receive scant consideration, while the unusual will pique our curiosity and absorb our attention. This would be an ideal arrangement if the treatment of the common conditions had reached a stage of perfection and could be automatically applied. But unfortunately this is not the case. Consequently it pays us to look at the medical condition that confronts us every day with the same inquiring mind which we bring to the scientific curiosity. Let us look in this light briefly at some of the problems of peripheral arterial disease. These disorders are among the most common ones in adult medicine; their intelligent treatment often saves the extremity, sometimes the life of the patient, and yet there is scarcely any field more frequently neglected by the practitioner or even by the textbooks of medicine.

PROBLEM I

The Diagnosis of Local Circulatory Impairment.—As an essential prerequisite to all other questions, the first problem to occupy our attention is how to diagnose local circulatory impairment. How do we determine that a given patient has a deficient blood flow in the extremity? This fact is established not by the application of any intricate apparatus but merely by the simple methods of history taking and physical examination. A deficiency of blood supply in the extremity sufficient to be clinically significant evidences itself in one or more of the following ways: (1) Sensory manifestations, particularly pain, but also coolness and paresthesias. (2) Abnormal color changes in the skin, particularly rubor in dependency and cadaveric

pallor on elevation. (3) Retardation of the return in the capillary circulation. (4) Trophic changes, the most extreme of which is gangrene.

There are two characteristic types of pain manifest in vascular disease. One of these is *rest pain* a severe burning sensation coming to the patient after a period of immobilization and elevation of the foot, usually when the patient lies down, and often particularly intense at night. This rest pain can usually be reproduced artificially by holding the feet in a high elevated position for a few minutes. For its relief the patient may have to hang the feet over the edge of the bed or actually get up and walk about the room. The second type is *exercise pain*, an increasingly intense aching produced only by muscular effort, usually walking until the continuance of the exercise becomes intolerable. If the main calf muscles are involved, then this exercise pain takes the form of claudication but if only the small intrinsic muscles of the foot are concerned, it begins as a sense of fatigue but becomes a painful aching in the foot. In either case it usually can be reproduced artificially by the patient vigorously flexing and extending the toes and foot in a vertically elevated position. A short rest period is essential to overcome such exercise pain, though it may be only a few moments' pause in walking. It is especially this exercise or claudication pain that must be distinguished from the pain caused by mechanical strain. Often the patient with peripheral arterial disease first consults the orthopedic surgeon thinking his pain is due to flat feet. And arterial disease and static deformities are frequently present in the same patient. By careful analysis of just how the pain is brought on and how it is relieved its cause

can usually be distinguished. Surely there is no excuse today for the physician to fail to recognize the vascular basis for typical intermittent claudication. Local circulatory impairment usually sooner or later causes either rest or exercise pain. Either associated with it or as an earlier symptom a sensation of coolness or paresthesia may be present.

Although these sensory abnormalities, especially pain, play an important rôle in calling the *patient's* attention to the fact that he has a condition which demands care and in suggesting the vascular basis to the *physician*, they are often far from specific. It is particularly on the basis of the physical signs which can be elicited that a deficiency of the local circulation is either established or ruled out. In the first place we always determine whether there is a good pulsation in the peripheral arteries, the dorsalis pedis and posterior tibial in the foot, and if absent here go to the popliteal, the femoral or even up to the iliac until definite arterial pulsation is felt. If there is no palpable pulse below the femoral triangle, there is almost always a deficient circulation in the foot. But though absence of pulsation in the two main arteries of the foot is evidence of arterial disease, frequently it is compatible with an efficient local circulation carried on through small collateral arterial channels; and a serious deficiency in the local circulation due to occlusion of the terminal vessels may be present, even though good pulsation is felt in the dorsalis pedis and posterior tibial arteries. How then do we clinically establish the existence of significant circulatory impairment? There are three signs that are particularly valuable. All three of them bring out in visual form the physiological response of the skin circulation. The first is *dependent rubor*, an intense reddish or plum coloration that appears in the toes and spreads upward for a variable distance when the foot is put in dependency. It usually takes several minutes to develop the maximum depth of color. Of course, a normal foot in a dependent position assumes a slightly pinker color than when it was horizontal but dependent rubor is well beyond the response of a normal circulation, and is always pathological. The next sign may be considered as the reverse of dependent rubor. It is a cadaveric pallor that appears in the foot with deficient circulation when the leg is elevated from the horizon-

tal to the vertical position. It may develop very quickly or require several minutes of elevation to be brought out, depending on the degree of impairment in the local circulation. In order to provide a rough measure of the degree of circulatory impairment existing, Buerger, a number of years ago, made use of the angle at which circulation in the foot was just maintained. This he named the angle of circulatory sufficiency. In the most severe grades of impairment this position is actually below the horizontal. The response of skin color to elevation is probably the most valuable single sign in the detection of less extreme degrees of local circulatory impairment. Exercise of the foot in the elevated position is of great assistance here in hastening the development of the characteristic pallor.

The third method of estimating the functional response of the local circulation is to measure the time that it takes for the return of skin color after temporarily blanching an area by pressure. This is called the capillary return time. Obviously it will vary not merely with the circulatory efficiency but also with the size of the compressed area. Consequently it is essential to apply this pressure to about the same size of area each time. Minor variations are not of importance. One learns to recognize about how fast the return color progresses under normal conditions from the periphery to the center. When the local circulation is seriously impaired this return of blood to the skin capillaries becomes very slow, and it is perfectly obvious that the head of arterial pressure effective in this area is very low, indeed. This capillary return test can be used in the horizontal position or at various angles of elevation where it furnishes a further refinement in testing the angle of circulatory sufficiency.

All three of these tests based upon the effect of certain factors on the color of the skin have limitations beyond which the normal reaction does not go. We can compare the performance in any individual patient with this normal reaction and say that it is, or is not, within the normal limits. Fortunately in vascular disease, we can also compare the response in one extremity with that in the opposite one. Although in most of the common vascular diseases the arteries of both extremities are involved, usually one of them has a greater degree of circulatory impairment,

so that its response can be compared with that of the more normal one. These color changes associated with variations in posture and following compression are the most specific evidences of local circulatory impairment. However, the latter also is associated frequently with trophic disturbances ranging all the way from slight glossiness of the skin or irregularities of the nails to gross necrosis of tissue. Massive gangrene is, of course, evidence of complete failure of the circulation, at least to the involved area, but it is then too late to save the gangrenous part, though amputation of the entire limb may not be required if spreading infection from the necrotic tissue can be prevented. By the application of the foregoing methods, it is possible to diagnose local circulatory impairment, and this is the first step in the handling of any type of peripheral arterial disease. There are of course certain diseases, such as Raynaud's disease, in which the circulation is impaired initially only during ischemic attacks, while between the attacks there is no evidence of deficiency in the blood flow. Typical examples of these conditions can usually be recognized from the history and the circulatory disturbance verified by observation of the patient in an attack.

PROBLEM II

Differentiation of Vasomotor Spasm and of Mechanical Occlusion—After it has been established that local circulatory impairment exists, the next important point to determine is its cause. Careful examination of the palpable peripheral arteries will usually show by an absent or diminished pulsation or by a sclerosis of the vascular walls whether there is evidence of organic disease. Most of these patients consulting their physician have evidence of such organic disease. Until the last decade this was considered proof that the circulatory disturbance was on a mechanical basis due to actual occlusion of the arteries supplying the part. Recently, however, the importance of collateral circulation in organic peripheral arterial disease has been rediscovered. The main arteries to the foot may be blocked, and yet circulation entirely efficient for its nutrition under ordinary conditions may be obtained. This is due to the blood supply through the small anastomotic channels which carry the circulation past the obstructed point. The condition of the

smaller vessels comprising the collateral circulation then becomes a matter of great importance. The nutrition of the foot depends upon the preservation or enlargement of these small channels. Normally the latter are subject to a vasoconstrictor tonus. We find, however, that there is a compensatory mechanism which abolishes this tonus when a sufficient degree of circulatory impairment arises. Thus in the ordinary arteriosclerotic disease when the nutrition of the foot is endangered, it is usually impossible to demonstrate any persisting vasoconstrictor tonus. In conditions associated with an inflammatory reaction extending through the wall of the vessel there is often, at least in one stage, a serious circulatory impairment in the foot which can be reduced by eliminating the vasomotor innervation. It consequently becomes of great importance to determine in any individual case what proportion of the deficiency in peripheral blood flow is due to vasoconstrictor spasm and what to mechanical occlusion. This we have most simply and reliably found to be demonstrated for the lower extremity by blocking the posterior tibial nerve temporarily with novocaine. If the circulation to the foot (shown not only by surface temperature determinations for the purpose of an accurate record, but also by obvious visual and palpable evidence) is notably improved following this procedure, then vasomotor impulses are contributing a clinically significant amount to the serious circulatory impairment in the extremity. This differentiation serves as a rational basis for treatment. If occlusion alone is responsible for the circulatory impairment then our measures are directed only toward making as efficient as possible the reduced blood flow and preventing any further impairment in so far as possible. This is the conservative treatment of vascular disease which often accomplishes a great deal for the patient and saves many limbs that without its detailed and meticulous use would be lost. Rest, protection of the extremity from cold and trauma, the vascular exercises proposed by Buerger and adopted with variations in practically all of the large vascular clinics of the country, the administration of fluids either by mouth or intravenously, and the complete prohibition of the use of tobacco in thromboangitis obliterans are the fundamentals of the physical part of this treatment. Fully as important as

any of the above, however, is to give the patient a philosophy of life which will enable him to live within the limitations prescribed by his condition. On the other hand, when spasm is proven by test to play an important rôle in the circulatory deficiency, then the complete elimination of vasoconstriction by lumbar sympathetic ganglionectomy for the lower extremity provides lastingly the same, or sometimes a little more, improvement in the local circulation as is temporarily produced by the nerve block test. Whether operation is indicated has to be decided for each case in this group on its merits. However, I will say that when the cases are meticulously chosen and confined to those shown to have an important element of spasm, the patients have been uniformly most gratified by the results. Even here, however, there usually is a limit within which the patient should stay. Thus, if claudication was present before operation, it usually persists after operation, though nearly always there is a considerable increase in the amount of exercise required to bring it out. Periarterial sympathectomy is of little or no value in this condition. The final position of sympathetic ganglionectomy in the treatment particularly of thrombo-angiitis obliterans will probably not be established for several more years; but in our hands by the careful selection of cases, it has been of definite value for the group to which it is applicable.

PROBLEM III

Manifestations of Vasomotor Neuroses Secondary to Other Lesions.—Many lesions primarily or secondarily involving the central or peripheral nervous system are associated with interesting vasomotor phenomena. Such symptoms are often entirely overlooked. They are worthy of clinical investigation for the light they can throw upon the relationship of sympathetic irritation to the primary diseases. Thus, long-standing paralysis from anterior poliomyelitis is often associated with a cold clammy extremity. This is also found in certain cases of spina bifida, in organic nervous diseases such as amyotrophic lateral sclerosis, and in certain functional nervous disorders such as hysteria. It is also observed in association with typical causalgia following a partial peripheral nerve lesion and with the neuritis produced by a cervical rib. In all of these instances in addition to the tendency toward a

lower temperature in the involved area and a sensation of coolness, there is usually a painful hypersensitivity to cold and sometimes increased sweating. Rarely, except in causalgia, does this vasomotor neurosis reach a sufficient degree so that it demands treatment. It should be of interest to the neurologists. It is also of considerable interest to us as it throws light on the next group which presents an important clinical problem.

PROBLEM IV

The Recognition of Important Vasomotor Reflex Disturbances Following Trauma and Its Repair.—As the result of trauma, there occasionally arise certain striking clinical pictures of reflex vascular disturbances. There are three different types of this which we recognize. The first one is a paroxysmal angiospasm resembling very closely a Raynaud's disease in which the involvement is limited to the traumatized area or the peripheral field of distribution of an injured nerve trunk. This is a good illustration of a greatly increased reflex hypersensitivity to cold, which outlasts by months and years the other evidences of the trauma. The second type of post-traumatic reflex disturbance was described by Leriche as "traumatic arthritis." I choose to refer to it as "reflex traumatic arthritis" in order to distinguish it from the mechanical type of arthritis which results directly from gross trauma inflicted upon the joint itself. Fontaine and Hermann have recently discussed this clinical condition under the name of "post-traumatic painful osteoporosis." The trauma which incites the condition may be a major single injury of considerable magnitude or it may be repeated lesser insults. There are two characteristics of the clinical picture, namely, pain in the joint particularly on its use, and an extreme progressive osteoporosis which is not associated with infection. There are often other evidences of vasomotor irritability such as an increase in sweating, coolness and clamminess of the toes, etc. The third type of clinical picture induced by trauma resembles the previous one, except that in place of osteoporosis there is an extreme degree of edema usually associated with severe pain and not dependent upon any gross blockage to the main blood vessels. For all three types of reflex traumatic neuroses conservative treatment consisting in protection from cold, rest at first followed by

graduated exercise, and contrast baths, is usually effective in controlling the symptoms in the mild and moderately severe cases. In the very severe cases it probably is advantageous to interrupt the vasomotor reflex arc by surgical intervention. And in this case periarterial sympathectomy is worthy of a trial followed by ganglionectomy later if the simpler operation does not relieve the symptoms. The importance of this group is not only in the isolated examples of a striking clinical condition that may lead to serious disability unless properly treated, but perhaps even more in the recognition of vasomotor disturbances as a fundamental type of response to trauma and its repair.

PROBLEM V

The Responsibility for the Immediate Recognition of Embolism in the Extremities—Embolism is a more common cause of circulatory impairment in the extremities than is generally realized. Larger emboli blocking the iliac, the femoral, the subclavian, or the axillary arteries almost always cause a serious disturbance in the circulation of the foot or hand, and frequently lead to gangrene unless removed. Key, to whom much of the credit is due for advances in this field of surgery, in 1929 collected and analyzed 216 cases of embolotomy in the extremities. If the embolus is removed in the first six hours, the results are good, while with each hour's delay after this time the probability of a recurrent thrombosis at the site of the embolus increases rapidly. After twenty-four hours it is scarcely worth while to do an embolotomy. The ideal result that can be obtained when the time between the occurrence of the embolus and its removal is minimal is shown by the following case.

W. A. aged seventy, was convalescent twenty six days after a suprapubic prostatectomy. He had arteriosclerotic and hypertensive heart disease accompanied by auricular fibrillation. And at one time after operation he developed some pulmonary edema. All cardiac symptoms had disappeared, though some irregularity of rhythm persisted. He was up and around and was merely waiting for his suprapubic catheter to be

removed. popliteal, dorsalis pedis and posterior tibial pulsations were absent, and the femoral pulse was felt only in the upper part of the femoral triangle. The left foot and lower leg presented an extreme pallor and were much cooler than those of the opposite extremity. The patient could not move his foot. The diagnosis of an embolus in the femoral artery

was made. Two hours after the development of the first symptoms it was removed with complete restoration of vigorous pulsation in the peripheral arteries and the relief of all symptoms. In spite of the fact that the femoral artery where it was opened to remove the embolus showed marked sclerosis with some calcification in the walls he has had no evidence of thrombosis. It is now seven months since embolotomy.

In view of the extreme importance of removing the embolus within the first few hours, the responsibility for recognizing the occurrence of this condition rests upon every practicing physician. Fortunately if this possibility is kept in mind the diagnosis of embolism in a major artery is usually not difficult. The patient notes the sudden occurrence of an unusual sensation in the extremity. Most often this is a sharp pain which may then rapidly increase until it becomes severe. Sometimes, however, the abnormal sensation is a tingling or a coolness. Any such history imperatively demands immediate investigation. On examination in such a case pulsations are absent in the arteries past the site where the embolus has lodged. And an obvious decrease or absence of blood flow to the distal part of the extremity is usually easy to recognize. Occasionally when the onset of symptoms is not so abrupt one may doubt whether the arterial lesion is embolism or thrombosis. In such a case if the patient is seen within ten hours of the onset of symptoms it is wise to proceed on the assumption that it is an embolus. Usually the delay in operation is not due to the difficulty in diagnosis, but it is caused by the failure of the physician to consider embolus or frequently by the procrastination of the patient in calling a physician. Most instances of major peripheral embolus occur in patients with cardiac lesions and especially in those who at one time or another have fibrillated. Consequently it seems advisable to warn all such patients that if pain or other unusual sensation should occur suddenly in an extremity the physician should be immediately notified. As embolism occurs nearly always as the complication of a serious lesion and as this process may take the form of multiple clots lodging in the same extremity or in various regions, immediate operation will not always be successful or in some cases even advisable. However, the obtaining of prompt operation by a surgeon well versed in the modern technic of vascular surgery will save many extremities in which gangrene develops following embolus.

THE MANAGEMENT OF UTERINE BLEEDING

THOMAS P. FARMER, M.D.

Syracuse, N. Y.

Uterine bleeding is a very common gynecological condition and one which the general practitioner most frequently encounters. Considered from the seriousness of its direct and indirect results it is the most important manifestation of gynecological disease which comes to his attention.

Although the incidence of its occurrence is highest at the extremes of menstrual life it can and does occur at any age period from infancy to senility. A fairly large number of patients showing this symptom may be classified as very elderly women. One interesting type of bleeding occurs several years after the menopause with an apparent normal return of menstruation as well as sex characteristics. In these cases the endometrium shows hyperplasia such as is seen at times near the menopause. This condition is due to an ovarian tumor whose structure is composed of an abnormal overgrowth of follicular elements. The tumor, while malignant in character, offers excellent chances of cure.

The term uterine bleeding is preferable to uterine hemorrhage as it is more inclusive. The amount of bleeding bears no relation to the seriousness of the condition responsible for it. Consequently, slight bleeding is as important as profuse hemorrhage, if not more so. While profuse hemorrhage demands prompt and adequate care, slight bleeding is frequently ignored by the patient and too often by the physician. Even when the underlying condition is not of a serious nature, the anemia resulting from slight but protracted bleeding may be more resistant to treatment than that due to profuse hemorrhage, where the recovery is usually prompt and complete. The physician has a grave responsibility in all these cases and the only safe policy for him to accept is that no uterine bleeding, no matter how slight, should ever be neglected.

Uterine bleeding is sometimes classed as physiological and pathological. Properly speaking the only bleeding which could be classified as physiological is menstruation. Menstrual blood shows marked differences from the blood of the body. The red cells

and leukocytes are decidedly less, and the hemoglobin much lower. In addition to admixture of epithelial cells and mucus, menstrual blood contains glycogen, lipoids, arsenic, magnesium, phosphorus, and calcium. Its principle distinguishing feature is its lack of coagulability. Consequently, this is not bleeding in a true sense of the word. Undoubtedly, menstruation may be increased in amount or prolonged and still be physiological. However, very frequently there is the additional factor of real blood loss, so that the condition is pathological. It would, therefore, seem wise to view as uterine bleeding any abnormal bloody discharge from the uterus and to consider this as pathological until proven otherwise. No definite standards can be formulated as to what constitutes uterine bleeding. Variations from the normal type and cycle of menstruation are more important than the actual amount and duration of blood loss.

The management of uterine bleeding consists in ascertaining the cause of this symptom and correcting the condition responsible for it. The conditions associated with uterine bleeding may be divided into two large groups as to whether or not there is an existing, or has been a recent, pregnancy. The conditions associated with pregnancy are responsible for the largest number of cases of uterine bleeding occurring during the reproductive ages. This group may again be divided as to whether the bleeding occurs in the latter period of gestation when the pregnancy is most apparent, or in the earlier period where pregnancy may not be evident or suspected. The first group includes placenta praevia and abruptio placentae, both of which require proper obstetrical treatment and are not within the limits of this discussion. Within the second group are abortion, ectopic pregnancy, hydatidiform mole, and chorioepithelioma. As has been mentioned, the diagnosis here may be complicated by the fact that the patient is unaware of an early pregnancy, or may possibly try to deceive the physician as to the existence of such a condition.

Abortion should rarely be diagnosed incorrectly and should be treated either conservatively, or by a pack, or by removal of the remaining gestational products, either manually or by the curet. No active interference should occur if there is associated fever, unless the bleeding is profuse or protracted. A histological examination of the curettings should always be made.

Uterine bleeding of various types is usually observed in ectopic pregnancy. Often it may be the principal complaint, and occasionally the only symptom. Though the diagnosis should nearly always be made in the sudden tragic cases, it frequently is not made in the more chronic cases. While the age of the patient, a history of previous sterility, abnormal pregnancy, a previous operation, a period of amenorrhea, spotting of blood, and attacks of colicky pain in either side, frequently associated with syncope, should suggest this condition, it is well to remember that the most typical thing about ectopic pregnancy is that it tends to be atypical.

Mole, while not frequent, occurs commonly enough to be met by the general physician now and then as a cause of uterine bleeding. It is necessary that one should be sure that the mole has been completely passed. Bleeding after the passing of a mole is highly suspicious of the existence of the rare but markedly malignant tumor, chorioepithelioma.

The second group in which there is no recent or existing pregnancy comprises a large list of important conditions as follows:

- Functional conditions.
- Endocrine disturbances.
- Constitutional diseases.
- Inflammation.
- Malpositions.
- Benign tumors.
- Malignant tumors.

Functional conditions are probably always due to some endocrine disturbance so that these two groups can be discussed together. It is to be expected that the onset and abatement of menstrual life should be accompanied with functional irregularities, including abnormal bleeding. While this principle may be accepted, without undue hazard in treating the menorrhagia of adolescence, it is entirely unsafe in the management of patients at or near the menopause, until organic disease has been ruled out by careful examination including biopsy. It was hoped that our newer

knowledge of the physiology of ovulation and menstruation, together with recent information concern the action of the anterior hypophysis, would be most helpful in these functional disturbances, but it has failed to do so. The marked and striking results following the injection of these extracts into animals, have not been paralleled in patients. Clinical symptoms do not form a reliable method by which variations in the amounts of hormones in the blood can be determined. We lack knowledge as to absorption, assimilation and elimination of these hormones when injected. We also know that tremendous doses are required to produce in humans, effects which have been noted in animals, and that some commercial preparations of these hormones show a marked tendency to deterioration. Possible dangerous effects following their use has not been properly appreciated. The psychic effect has been lost sight of. It is, therefore, not surprising that at the present time the consensus of well-informed opinion is that the substitution therapy for functional disorders is of little value. It is to be regretted that its clinical application has outstripped its experimental investigation.

The diagnosis of a functional cause of the menorrhagia of adolescence is usually made by a process of elimination. The majority of these cases are best treated in a conservative manner, after the condition has been fully explained to the patient or her parent, by instituting the proper hygienic régime with the use of tonics, and pituitrin at the time of severe bleeding. As a matter of fact, many of these cases take care of themselves spontaneously. At times, a curettage will be necessary and rarely this may have to be repeated. Radium in small doses should only be resorted to in the very exceptional case which fails to progress satisfactorily under other forms of treatment, and then should be used with extreme conservatism and by one fully experienced with its effects. Some of these cases are due to hypothyroidism. When this has been determined by approved methods, thyroid extract may be administered. Without doubt the relation existing between the thyroid and gonads is a close and varied one because both menorrhagia and amenorrhea occur with hypothyroidism and menorrhagia occurs in both hypo- and hyperthyroidism.

Glandular hyperplasia of the uterus is included in this group as it is believed by

some that it is due to abnormal ovarian hormone activity. This condition is responsible for most of the bleedings occurring at or near the climacteric, which are not due to fibroids, polyps, or malignant disease. The bleeding is usually quite profuse and very protracted with the result that the patient not only suffers much inconvenience, but also develops a marked secondary anemia and general poor health. The histological appearance of the endometrium removed at curettage is quite characteristic and forms the basis of the diagnosis. When this condition is present at the menopause, it is promptly and permanently cured by radium. Although it is by no means definitely proven that it frequently occurs, adenocarcinoma has been observed developing on a glandular hyperplasia. Therefore, it seems advisable that a patient in the menopausal age, presenting this condition, should have radium therapy not only to control the bleeding but possibly as a prophylactic against the future development of cancer.

Heart disease, nephritis, hypertension, anemias, especially of the chlorotic type, and purpura, may cause uterine bleeding and should always be thought of when such bleeding exists. The bleeding, if due to any of these causes, usually subsides under proper treatment. Two young individuals with profuse uterine bleeding due to purpura have been admitted to my service at St. Joseph's Hospital. Both rapidly improved after they had received transfusions and a few injections of pituitrin together with proper medical care. I have since learned that one of these cases died at home in a subsequent attack from a hemorrhage in the brain.

Among the inflammatory conditions which may cause uterine bleeding are salpingitis, subinvolution, and lacerations and erosions of the cervix. Naturally, the appropriate treatment of these conditions is indicated for the relief of other symptoms as much as the bleeding. Bleeding seems to be more prominent in those cases of salpingitis where the ovaries are especially involved and where the uterus is pulled back by strong adhesions.

Bleeding may occur in some cases of retroversion. This is probably due to the passive engorgement of the uterus which has resulted from an obstruction of the circulation of the pelvic veins. An associated prolapse is probably as much responsible for this condition as the more ap-

parent retroversion and with its usual trail of symptoms demands relief as much as the bleeding.

The benign tumors of the uterus are responsible for many cases of uterine bleeding. It is well known that fibroids are very common tumors, it being estimated that they occur in from 20 to 50 per cent of all women at different ages. They comprise from 4 to 8 per cent of the material in gynecological clinics. In at least one-third of all large fibroids bleeding is the cardinal symptom. Eighty-five per cent of these are submucous fibroids. It is important to remember that fibroids are slow in growth manifesting symptoms during the latter part of menstrual life, that they are very prone to degeneration and that cancer of the body of the uterus shows a higher incidence in the fibroid uterus than in the normal uterus. The treatment of fibroids causing bleeding depends on many factors. Myomectomy is the treatment of choice in young women in order to preserve function. Because of their particular tendency to degenerate, large fibroids should always be removed. However, at or near the menopause, fibroids of moderate size, not producing pain but causing bleeding, should be treated by radiation. It is imperative that this should always be preceded by curettage. Inasmuch as in these cases bleeding is the symptom demanding relief, radium is preferable to x-ray. It has the added advantage of usually completing the treatment at one time. Submucous fibroids and fibroids associated with infections should never be treated by radiation. Polyps, either cervical or corporeal, are also a frequent source of uterine bleeding. The similarity of the history in these cases to that of cases of cancer is most marked. Except for polyps originating near the external os which can easily be removed, the cervix should be dilated and both the cavity of the body and the canal of the cervix curetted, as polyps are frequently multiple and cancer of the body may also be present. The cervix should also be cauterized. Adenomyomata which also cause bleeding are not suitable to myomectomy but require a hysterectomy. Benign ovarian tumors have little effect on uterine bleeding, though it is possible that microcystic disease of the ovaries may be responsible for some cases.

Uterine bleeding occurs practically always in malignant disease of the uterus. This valuable manifestation of this most

serious condition should be more properly evaluated and made use of by the physician for the purpose of early diagnosis. Marked differences exist between cancer of the cervix and cancer of the body of the uterus. Cervical cancer is at least four times more frequent, occurs at an average age ten years earlier, metastatizes much earlier, and shows a decided lower percentage of cures than does cancer of the body. Cancer of the cervix is usually an epithelioma while that of the body is adenocarcinoma. Cancer of the cervix occurs almost exclusively in multiparae and the bleeding is of a contact type. Cancer of the fundus is distinctly a postmenopausal disease, practically 75 per cent of the cases occurring during the sixth and seventh decades. It is needless to say that the early treatment of cases of uterine bleeding due to these causes is most imperative. The majority of cases of cancer of the cervix are now being treated with radium. Cancer of the fundus offers reasonably good chances of cure following a hysterectomy. Nevertheless, corporeal cancer is as malignant as cervical cancer. The higher percentage of cures of cancer of the body is due largely to the protection of the myometrium against the advance of the growth. Sarcoma of the uterus is practically always accompanied by uterine bleeding, though frequently there is also a characteristic profuse watery discharge. Treatment of this

condition is not highly successful. Cancer of the ovary metastatizes quite early to the uterus and therefore is frequently accompanied by uterine bleeding. Unfortunately, cancer of the cervix in a large percentage of cases has progressed to such an advanced stage as to make accurate diagnosis possible by palpation and inspection. All suspicious early cases should have a biopsy done. Cancer of the body offers no characteristic physical signs, examination frequently being negative. Consequently, curettage is necessary for diagnosis, about 20 per cent of unsuspected cases being found in this manner.

This rather extensive and superficial review of the conditions associated with uterine bleeding has been given in order to show the wide variety of causes of this condition. It has also been the purpose to indicate the seriousness of several conditions which manifest themselves by uterine bleeding as much as in any other way. The physician should always realize his responsibility in treating cases of uterine bleeding. This responsibility increases as the patient's age approaches the menopausal period. Nothing short of a positive diagnosis as to the cause of uterine bleeding should ever suffice. Curettage and the removal of cervical tissue are the only sure means of diagnosis. Radiation treatment for uterine bleeding should never be employed until cancer has been excluded.

THE THOMAS W SALMON MEMORIAL LECTURES

As announced in the February 1 1934, issue of the *JOURNAL* the chosen lecturer, Dr C MacFie Campbell, Professor of Psychiatry at Harvard University, will deliver three lectures on April 13th, 20th and 27th at 830 P M at the New York Academy of Medicine, 2 East 103rd Street, New York City.

The subject of these lectures is Trends in Psychiatry. Brief abstracts for each lecture have been received and are here presented as follows.

Lecture 1 Trends in Psychiatry A discussion of the various methods of approach during the past thirty years and of the varying emphasis laid by different individuals on different factors in the whole field. Reference to the importance of histopathology, the infectious theory, the biochemical investigations, psychoanalysis, Meyer's broad and well integrated formulation. This lecture would be a discussion of trends with some evaluation of the drift of opinion. It would show some of the progress of thought during the life time of Thomas Salmon.

Lecture 2 Classification vs Dynamic Analysis

A presentation of factual material with analysis into sub groups, review of the actual stuff of life presented by these sub groups. Subordination of classification and verbal discussion to observation and reduction of the concrete problem to biological components and constitutional factors.

Lecture 3 Conclusions and Suggestions The orientation with regard to the field outlined in the first lecture and the review of the actual stuff of psychiatric work may suggest certain practical conclusions and may indicate directions of theoretical investigation.

One of the smallest x ray machines in the world, weighing only 7 lb and able to take perfect pictures in two seconds, was shown at the Congress of the British Institute of Radiology by Dr A Bouwers of Eindhoven.

Vitamins prepared in the laboratory fall short of expectations, declared Dr Chalmers Watson in an address in Edinburgh, and he recommended giving plenty of fresh foods as the best way to provide them.

New York, N. Y.

NEVI

The term birthmark as a synonym for nevus is somewhat misleading as the majority are not actually present at birth. Some do not occur in infancy, or even in childhood, and only appear in adult life. Vascular nevi strictly include those composed of lymphatic vessels, but the term is ordinarily used to denote lesions composed of blood vessels. From the standpoint of both treatment and prognosis there is an important distinction between the flat vascular nevus (port wine mark) and the raised hemangioma. A mild variety of the flat type is often seen at the nape of the neck in new-born infants, usually disappearing before the end of the first month. Remains of it often persist, however, in women throughout life. The flat type of nevus shows no tendency to change and is permanent. The raised vascular nevus (hemangioma or strawberry mark) is more common than the flat type. Hemangioma may be single or less often multiple and occurs fairly often upon the face.

The treatment of flat vascular nevi is unsatisfactory, especially when the lesions are extensive as in cases involving one side of the face. In my opinion no treatment of any kind should be attempted in such cases as the results are often worse than the original defect. It is always possible to make them paler by intensive use of the water-cooled mercury vapor lamp (Kromayer). It is exceedingly difficult, however, to treat a number of small circular areas and produce a uniform lessening of the color. Too often an unfortunate patch work appearance is the result. Hemangiomas, on the other hand, are very amenable to treatment either by freezing with carbon dioxide snow or by radium. One of the types of cryocautery can be used for freezing, though the degree of cold is not equal to that of a crayon of carbon dioxide snow. In my opinion, there is often, if not invariably, a spontaneous involution of these lesions because, in spite of their comparative frequency in infants, they are not seen in adults. Many are treated, though certainly not all of them. Frequently after

traumatism and bleeding, thrombosis takes place with subsequent disappearance of the nevus.

Pigmented and hairy nevi may be removed by various destructive methods such as carbon dioxide snow, electrodesiccation, electric cautery, or electrolysis. At times the lesions are so extensive that treatment is out of the question, as in cases occupying large surfaces of the body such as the so-called "bathing-trunk" type. In one of the writer's cases of the latter variety there was an association of lipomatous nevi about the genital region which were excised by the knife.

PSORIASIS AND HERPES ZOSTER

Psoriasis and herpes zoster are examples of skin disease which affect both children and adults, but which are nearly always of comparatively mild type in children. While psoriasis may begin in the later years of childhood, it is usually of superficial type with comparatively little thickening of the skin or masses of typical micaceous scales. The writer has never seen a child with the severe inveterate type so common on the extensor aspect of the extremities in adults.

Herpes zoster occurs in childhood but is not accompanied by the severe neuralgic pain of which many adults complain. Comby states that herpes zoster in children under ten years of age invariably runs its course without any pain. The indications for treatment are to relieve pain and protect the vesicles from rupture and possible secondary infection. In children it is only necessary, as a rule, to protect the lesions by a bland dusting powder such as talcum or by painting the surface with flexible collodion. Vesicular eruptions in general should not be covered by ointments as they tend to macerate and rupture the lesions and thus lead to infection and subsequent scarring.

PITYRIASIS ROSEA

Pityriasis rosea affects both children and adults and in any case is a self-limited affection which runs its course in five to ten weeks and rarely recurs. The chief importance of the disease lies in its dif-

ferentiation from the macular eruption of acquired syphilis which is a rare manifestation in childhood. The chief differential point is that the macular syphilide is free of scales while pityriasis rosea as its name would imply presents branny scaling. In perhaps half of the cases there is an initial patch which is usually circinate in configuration. The general eruption appears rather suddenly, almost like an exanthema and varies in profuseness and in type. The majority of cases present round or fusiform macules or maculopapules with a moderate amount of branny scales. The less common type consists of circles with pinkish border and yellowish brown center. The disease occurs chiefly upon the trunk. Itching varies and may be absent, mild, or at times severe.

Treatment shortens the course of this harmless disease, the author's favorite method being a modification of that suggested by Jamieson. After a daily prolonged warm bath, an ointment of 3 per cent salicylic acid is rubbed into the affected areas. In ten days after such treatment the greater part of the eruption usually disappears.

RINGWORM

Ringworm of the scalp, in the form of coin-sized scaly patches covered by short broken hairs, is caused by some species of microsporon and is easy to recognize. The presence of ringworm of the scalp due to a trichophyton is, however, often overlooked as it occurs in small scaly areas which are mistaken for seborrhea. Epilation by x-rays constitutes the quickest and most reliable method of treatment. In the hands of experienced operators using standardized apparatus, it is also safe. Epilation by oral administration of thallium acetate was first introduced in Mexico City, Dr. Gonzales Herrejon being the first to standardize the dosage. By 1930, Dr. Cicero had treated 900 cases and Dr. Gonzales Uruena had treated 600 cases by this method without any untoward results. It has also been successfully used in numerous clinics in this country including the author's own at New York University. It would be an ideal method of treatment if it were invariably safe. In the past few years, however, a number of deaths have occurred in England, Germany, and Spain in children who were treated by this method. The possibility of causing death in a disease which is essentially harmless and which

nearly always disappears spontaneously at puberty is sufficient in my opinion to condemn the use of thallium acetate. Furthermore, the drug has certain contraindications and extreme care must be used in calculating the dosage in relation to body weight. Its use in the United States has been practically discontinued.

PEDICULOSIS

Among cutaneous infestations of worldwide distribution pediculosis capitis is always common, especially in the poorer classes. Of the three types of pediculosis, only that which affects the scalp is common in children. Body lice are seldom seen in children and pubic lice are only seen at times upon the eyelashes. The signs and symptoms of pediculosis of the scalp are too well known to warrant their description. It is not generally known, however, that this affection which is so common in white children of the poorer classes is comparatively rare in the negro. In a survey of school children in New York City, made by the Department of Health, it was found that in a series of 28,000 children pediculosis capitis was 33 times as common in whites as in negroes. The cause of this comparative racial immunity is not known.

WARTS

Warts of various types are common affections of childhood, although they are not confined to this period of life. The ordinary verruca vulgaris or "seed wart" is familiar to everyone but is often difficult to remove, at least without producing a scar. In my opinion it is improper to cause unnecessary scarring especially on the hands of girls. For this reason we do not often use electrodesiccation for their removal and would not think of using nitric acid on account of its strong tendency to cause keloid scars. At times ordinary warts disappear after a single erythema dose of x-rays though failure often follows, even when massive doses of this agent are used. When common warts are situated about the nail folds, a trial with x-rays is worth while as it is difficult to anesthetize this region for treatment by the curet or electrodesiccation. A favorite method of the writer is to freeze the lesion with ethyl chloride spray protecting the surrounding skin with vaselin and then removing the lesion with a sharp bone curet. This is usually followed by permanent cure.

It is well known that common warts are

most capricious in their course and often disappear without apparent reason. They may disappear after mental suggestion, though this seems difficult to understand in view of the fact that they are caused by a filtrable virus. That these warts can be cured by mental suggestion has been proven beyond question by Bloch in a reasonably large series of cases.

The ordinary juvenile flat wart may be removed by a sharp curet without causing any scar. When the lesions are numerous, and at times there are one or two hundred or more, it is advisable to try the internal administration of protiodide of mercury tablets in doses of $\frac{1}{8}$ to $\frac{1}{4}$ gr. after meals. This will often cause a complete cure in three or four weeks without any other treatment.

Plantar warts are seen at times in children, though not as often as in adolescents or adults. Here the best results are obtained by massive doses of x-rays, some giving as high as seven or eight erythema doses of unfiltered irradiation, the lesions being closely screened by lead foil.

ALOPECIA AREATA

Alopecia areata is fairly common in childhood and at this period is as capricious in its course as in adult life. Although the disease was described by Celsus, we are as ignorant of its causation as was this early Roman writer. The presence of more or less completely bald patches without any redness, scaling, subjective symptoms or atrophic changes makes the diagnosis simple.

It is freely admitted that in a disease which usually disappears spontaneously, it is difficult to judge of the value of any curative measure. I feel convinced, however, that intense local stimulation often accelerates the regrowth of hair. For one or two small patches, painting with pure phenol is recommended, the procedure to be repeated at intervals of a week or ten days. For larger patches it is well to try intense irradiation with ultraviolet light, such as the ordinary air-cooled type of mercury vapor lamps. This merely represents a convenient and cleanly method of stimulation.

Following the recent publication of an article on the use of the anterior lobe of the pituitary gland in alopecia (mostly of the alopecia areata type), I gave this remedy a thorough trial. My results were absolutely nil and all of my dermatological

colleagues with whom I have discussed the subject have had similar results.

RARE DISEASES

Mention should be made of several uncommon or rare diseases of the skin which are of special interest. *Urticaria pigmentosa* is poorly named as it has no relationship whatever to ordinary hives. It is classed as a congenital anomaly of the skin and consists of yellowish brown macules of pea to small-coin size which are mostly present on the trunk. Upon vigorous friction the lesions may show an urticaria-like reddish elevation. The affection is entirely harmless causing no subjective symptoms and disappearing spontaneously around puberty. Treatment is of no avail.

Xeroderma pigmentosum is a rare affection of childhood which often occurs in more than one child in a family. It is essentially a precocious senility of the skin, the changes simulating those of old age or those of chronic radiodermatitis after improper use of x-rays or radium. Epitheliomas eventually develop and many die before adult life is reached. The skin shows a peculiar sensitivity to ultraviolet rays and it is always advisable to protect the exposed parts from direct sunlight.

Hydroa vacciniforme is thought to be another example of sensitivity to light in those whose tissues contain hematomorphoryn. The usual history is that of repeated attacks in the spring or summer of a vesicular eruption upon the exposed parts. Some of the lesions have a slight resemblance to vaccinia from which the name of the disease is derived. The eruption is often profuse and causes a good deal of distress. A peculiar feature is that after involution of the lesions more or less pitted scarring remains. In rare instances the scars are very deforming. According to Senear and Kink, hematomorphoryn is found in 17.5 per cent of the cases.

Epidermolysis bullosa is a congenital anomaly of the skin apparently due to absence of elastic fibers. It is one of the two diseases of the skin in which the essential lesion is a bulla, the other being pemphigus. The lesions of epidermolysis bullosa appear, as a rule, upon areas exposed to trauma and can be artificially produced by violent pinching of the skin. The affection gradually lessens in severity and has usually disappeared when adult life is reached. At times little milium-like

bodies are seen on the fingers and may cause dystrophic changes in the nails. Treatment consists simply in ordinary surgical care of denuded areas and in avoiding trauma.

The subject of *cutaneous indurations* in the newborn has long been a source of confusion, part of which is merely due to difference in nomenclature. The term "sclerema neonatorum" should be confined to infants with a generalized waxy, shrunk skin, extreme subnormal temperature followed in a few days by death. Such infants are small, often premature, while in other cases they are severely dehydrated following diarrhea.

In sharp contrast to the above mentioned affection (called *sclerema adiposum* by many continental writers) there is a benign type of induration in newly born infants which is more or less localized, though large areas may be affected. This has been called *subcutaneous fat necrosis* of the newborn. Possibly a better name is obstetric lipophagic granuloma, the fat tissue showing a granulomatous infiltration, often

following obstetric trauma. This affection is entirely benign and disappears spontaneously by the end of the third or fourth month without, as a rule, leaving any trace. While the disease is present the patients show no disturbance in temperature and gain normally in weight. The disease appears to be often due to trauma the infants being, as a rule, of good size and frequently born after difficult labor. At times unusually vigorous methods of resuscitation are thought to be of etiologic importance.

Scleroderma of new born infants is now known to be exceptionally rare. Many cases of subcutaneous fat necrosis were formerly described in the literature as *scleroderma*, but in such cases histologic examinations were not performed. Furthermore, *scleroderma* in adults never clears up in a few weeks or months as does fat necrosis. My interest in these types of subcutaneous induration is largely based on the opportunity of recently studying 5 cases of subcutaneous fat necrosis, 4 of them having been observed at the New York Nursery and Childs Hospital.

140 EAST 54TH STREET

A BANNER HEALTH YEAR

The death rate in this state dropped to the lowest point on record, 11.2 per 1,000 population in 1933, according to the State Health Department. In particular, the mortality from whooping cough, diphtheria, tuberculosis, and pneumonia were never known to be lower.

Deaths from scarlet fever and diseases of the heart decreased from the previous year, while mortality from alcoholism was the lowest in eleven years and from suicide and homicide the lowest since 1929.

Automobile accidents resulted in fewer fatalities than in seven years. Fatal accidents in general were lower only once before.

Increases were noted, however, in material mortality and deaths from cancer, diabetes, and measles.

Diphtheria prevention work was more successful in 1933 than ever before, the department reported.

Thirty eight of the sixty seven cities and villages of more than 10,000 population, three more than the previous year, showed that 35 per cent or over of children under five years of age were immunized last January 1st. This per

centage is considered necessary in order to protect a community against an outbreak.

Middletown in Sullivan county, again reported the highest percentage of children who were immunized—92 per cent.

Thirty one communities showed an increase in the percentage immunized as of last January 1st compared with the same day the previous year.

Communities reporting at least 35 per cent of children under five years of age immunized according to population:

100,000 to 250,000	Utica, Syracuse
50,000 to 100,000	Schenectady, Niagara Falls, Binghamton, New Rochelle
25,000 to 50,000	Newburgh, White Plains, Watertown, Auburn, Kingston, Poughkeepsie, Amsterdam
10,000 to 25,000	Middletown, Johnson City, Ithaca, Endicott, Ogdensburg, Port Jervis, Lackawanna, Hudson, North Tonawanda, Oneida, Geneva, Herkimer, Ossining, Little Falls, Peekskill, Tonawanda, Freeport, Port Chester, Lockport, Beacon, Cohoes, Johnstown, Corning, Mamaroneck, Rockville Center

The New York City Board of Health reports the lowest death rate in the history of the city, 10.23 per 1,000 population, in 1933. The largest number of deaths, 18,667 out of 75,153 total were due to diseases of the heart. Cancer followed with 8,929, then pneumonia,

7,679, tuberculosis, 4,057, Bright's disease, 3,639, and accidents, 4,234. The infant mortality rate was 53.2 per 1,000 births, an increase over 1932, when the rate was 50.91. Maternal mortality increased to 6.41 per 1,000 live births as against 6.09 in 1932 and 5.29 in 1928.

THE DIAGNOSIS AND TREATMENT OF TWO HUNDRED AND TWENTY-FOUR CASES OF GASTRO-INTESTINAL ALLERGY

WILLIAM LINTZ, M.D.

Brooklyn, N. Y.

A more intimate knowledge of gastro-intestinal allergy would save many a needless operation and a diagnosis of gastric neurosis with its concomitant life-long tragic suffering. Since there are so many doctors of more than twenty-five years in practice, experienced in allergy of the respiratory tract, *i.e.*, hay-fever and asthma, and yet who have never made a diagnosis of gastro-intestinal allergy, the question arises is there such a disease? The observations recorded in this paper, made from 224 office patients who have been under my care for the last eight years, answer this question in the affirmative. While allergy of the respiratory system, such as hay-fever and asthma, is frequently recognized, allergy of the gastro-intestinal tract is comparatively rarely diagnosed by the rank and file of our profession. Yet in my experience the latter condition is much more frequent than the former. These patients cannot be relieved except along anti-allergic lines. The difficulty lies in the fact that there are no pathognomonic symptoms or signs in gastro-intestinal allergy. Similar symptoms may arise from various gastric disturbances such as ulcers, gall-bladder disease, appendix, the various neuroses, etc.

HISTORY

The patient's history is of greater help in recognizing gastro-intestinal allergy than any other single procedure.

TABLE I

Females: Number of positive allergic family history 100, or 72.5 per cent.

Males: Number of positive allergic family history 53, or 61 per cent.

The reason why there is a greater positive allergic family history in the females than in the males is, I believe, because they remember the family history better. Sometimes the only positive allergic history to be obtained is in a grandparent and frequently only in an offspring. Neither of these sources of information should be ignored.

Allergy rarely manifests itself in a single organ or tract¹; in other words, if the patient is observed long enough, he will reveal not only gastro-intestinal symptoms

but other allergic manifestations of the skin, respiratory, genito-urinary and nervous system, such as migraine, etc. Other allergic manifestations in our group are shown in Table II.

It is observed that the most frequent association was allergy of the skin and then came asthma.

The vegetative nervous system plays a most important rôle in allergy² and it is rarely that only a single branch is involved; the other branches and the organs supplied by them soon become implicated.

TABLE II

Diagnosis	Totals
Allergy of gastro-intestinal tract.....	224
Allergy of skin.....	156
Asthma	63
Hay-fever	50
Migraine	42
Allergy of genito-urinary tract.....	15
Allergic arthritis	16

It is of great importance to obtain a history that certain foods or emanations are responsible for the symptoms. This is exceedingly difficult even when attention is drawn to it. Yet many patients will tell you that shellfish causes vomiting, meats diarrhea, white potatoes heartburn, bacon and eggs invariably give rise to "appendicitis." Oak pollen was responsible for abdominal pain, cramps, and indigestion, which were relieved completely by specific immunization therapy. Upon repeated observation, house dusting gave rise not only to eczema, but also nausea, gas, abdominal pain, and indigestion.

Very frequently the same article of diet will not only be responsible for gastro-intestinal allergy but involve other tracts as well, giving rise to rhinitis, coughs, asthma, hives, migraine, etc. Often a patient has a strong dislike for a certain food and gives a bizarre reason, "as I am not accustomed to eat it," etc., whereas the true reason is because he is allergic and is made mildly sick by it. I find that these patients who omit breakfast are frequently allergic to breakfast foods. When a patient can eat food prepared only in a certain way and when a certain food acts on the bowel, heart, etc. (milk acts as a cathartic, eggs cause palpitation), one should be on the lookout for allergy—as for example, "raw

milk makes me sick but not boiled or sour"

"a hard-boiled egg agrees but not soft-boiled or raw" "I cannot eat cabbage but I can take sauerkraut" Another help in the history is where self-imposed fasting improves symptoms At times one hears 'I have inherited a bad digestive system,' very frequently this was allergy of the gastro intestinal tract I have come across such a family of six members, although the allergy was not confined exclusively to the gastro intestinal tract A history of anaphylactic shock after serum injection is not infrequently obtained

When the digestive symptoms make their appearance, only on a certain day in the week and sometimes only on certain hours, allergy should be thought of This is very frequently associated with a religious or racial custom as when the Catholic becomes ill only on Friday due to fish and the Jew on Saturday morning after the feast late the night before A history of drug rashes is not infrequently obtained in these cases especially after salicylates, cinchophen, iodine, bromides, belladonna, etc A change in weather gives these patients not only pains in limbs attributed to rheumatism but makes them melancholic and depressed in general

One should be on the lookout for an allergic explanation of existing symptoms when a history of repeated attacks of exanthemata is obtained, especially in grown-ups Usually these are the misinterpretations of the associated allergy of the skin which as we see from Table II, is the most frequent combination of gastro-intestinal allergy

SYMPTOMS

This disease occurs mainly in the chronic form, and to a lesser extent in the acute form In both instances it may be mild, moderate, severe, continuous intermittent, immediate, delayed, or cumulative I believe the symptomatology may be best conveyed by citing actual cases illustrative of the various forms Between the mild and severe cases in both the acute and the chronic are numerous intermediate forms of varying severity

(1) MILD ACUTE—In mild acute allergy the patient is perfectly well with the

exception that upon eating certain articles of diet such as shell fish, strawberries, etc., he gets distress, gas, nausea, abdominal fullness, constipation or diarrhea. These are usually associated with skin manifestations as hives, rashes, etc. He knows that certain foods give him indigestion. With the exception of positive skin tests and rarely eosinophilia all investigations are negative.

Comment.—Cure is readily obtained by avoiding the interdicted article of food.

(2) SEVERE ACUTE.—F.S., female, age 23, with a previous history of attacks of measles, chickenpox, sore throat, mumps, tonsillectomy, and adenoidectomy, had a strong family history of allergy. She had been suffering for years from repeated attacks of singultus, coated tongue, bitterness, epigastric tenderness, nausea, gas, belching, abdominal distress, cramps, constipation, diarrhea, severe backache, headache, dizziness, nervousness, insomnia, pains in extremities, rhinitis, dry cough, dyspnea, palpitation, and extensive rashes of various kinds all over the body, frequency and dysuria, and irregular menstruation. The above symptoms came on in definite attacks, only after the ingestion of certain foods; in the intervals the patient was perfectly well while under the allergic régime. After a heavy meal of delicatessen composed of corned beef, pastrami, etc., the patient had a marked aggravation of the above symptoms, appeared acutely ill, temperature 105° F., pulse 120, with a marked diffuse abdominal tenderness over the lower half of the abdomen (no rigidity over McBurney's point or gallbladder), the leukocyte count was 31,000, polymorphonuclears 88, eosinophiles 1, small lymphocytes 9, large lymphocytes 2. With the exception of a secondary anemia and strongly positive skin tests, all other investigations were negative. This performance was repeated again and again.

Comment.—In acute allergy, as a rule, the temperature elevation, leukocytosis, and polymorphonucleosis are absent; the eosinophilia occasionally may be present. These patients frequently undergo needless surgery. This patient has been under the author's observation for the last eight years and nothing but food allergy was the final diagnosis.

(3) MILD CHRONIC.—F.V., male, age 35; previous history: nose operations and appendectomy. Family history: mother had

essential hypertension. The patient was suffering for years from gas, belching, constipation, sour taste, headache, exhaustion, colds and "catarrh" in the summer time. Skin is raw and rough, knows that cabbage gives a bitterness, constipation, and headache, onions indigestion, pie gas, etc. With the exception of positive skin tests, complete x-ray examinations of teeth and gastro-intestinal tract (which showed an overactive colon), gonorrhea complement fixation test, and Wassermann were negative.

Comment.—Patient was completely cured not by the appendectomy but by anti-allergic treatment.

(4) SEVERE CHRONIC.—N.M., age 49, female, previous history: hysterectomy, influenza, pneumonia, measles, and mumps. Family history: definite allergy. Patient was sick since the age of eighteen. She suffers tremendous distention, gas, eructations, severe abdominal pain, cramps, obstipation, perspires freely, severe backache, listlessness, depression, dizziness, nervousness, insomnia, weakness, precordial pain, cries, suicidal tendencies, dyspnea and palpitation, has intense itching all over body, anosmia and sterility; refused repeated operations. All teeth extracted with no relief. Knows that certain foods gave rise to the above symptoms. Physical examination was negative, skin tests positive, basal metabolism minus six, x-rays of gastro-intestinal tract and chest were negative, gonorrhea fixation and Wassermann tests, urine, gastric analysis and feces were all negative; complete blood with the exception of a secondary anemia was entirely negative.

Comment.—Extensive allergic involvement of nearly all tracts, complete cure of this life-long severe illness was made possible only under the allergic régime.

Symptoms presented by our 224 cases. (Table V).

COMMENTS ON SYMPTOMS

The longer these patients are under observation, the more symptoms they present; hence, when the time element is eliminated from the statistics, the frequency of the various symptoms presented is not constant and will vary with different observers.

Herpes labialis is a frequent allergic manifestation. I wonder whether the same lesion occurring in the gastric and duodenal mucosa and its subsequent digestion

by the gastric juice is not responsible for peptic ulcer¹

A very stubborn condition of unknown and dubious etiology is the coated tongue the itching soreness and rashes at the roof of the mouth the bitterness and soreness of tongue. This is frequently of allergic origin and may come on before the patient is finished with his meal or sometime after. To observe the miraculous disappearance of

this stubborn condition under the elimination of the specific allergin, after defying all alterations of dental appliances, is a gratifying result.

I have repeatedly observed constipation and obstipation caused by allergic foods. A mother noted repeatedly that oatmeal invariably caused constipation. Another woman with a life long history of obstipation and symptoms resembling duodenal ulcer with rashes, etc., all vanished under four days anti-allergic treatment and remained so permanently. Intestinal obstruction may be caused by angioneurotic edema of allergic origin. The writer knows of one such case that was actually observed on the operating table.

Cleven ulcer cases⁴ could not be cured by the Sippy or any other method, but gave an instantaneous response to the anti-allergic regime. The same held good with seven gallbladder cases. The writer wonders how many ulcer and gallbladder cases have an allergic etiology¹.

The relation to essential hypertension and allergy is discussed elsewhere⁵.

Bleeding from the various mucous membranes,⁶ nose mouth stomach, rectum, genito-urinary, and subcutaneous is a frequent manifestation of allergy (see Table VI). It may be macroscopic and extensive but is usually microscopic. Since capillary hemorrhage is one of the most frequent findings of allergy, this is to be expected.

Very frequently allergic symptoms can be reproduced by the ingestion of the suspected article of diet. Then it has diagnostic importance. If it is negative, it does not rule out allergy.

Backache frequently exceedingly severe and stubborn was present in 59 cases. The exact explanation is not clear to me. All of them were greatly helped by the anti-allergic regime.

The nose and sinuses are a frequent site of various allergic manifestations such as clogged nose pain rhinitis cloudy sinuses etc., and are not benefited by operations.

Overdoses of pollen inoculation for asthma and hay fever will frequently give rise not only to symptoms referable to the respiratory tract but also to gastro-intestinal symptoms. The allergin undoubtedly causes an overactivity of one or more branches of the vagus, causing contractions of muscle secretions, and vascularity and if widespread it will cause shock.

Not only do all kinds of rashes result from allergy but pruritus is frequently a

localized allergy of the skin. The nervous manifestations are a conspicuous symptom in this disease and are often of diagnostic value. Tinnitus, dizziness, vertigo, and deafness are frequently of allergic origin.

ENDOCRINES

The writer believes that the endocrine glands play an important rôle in all forms of allergy. Mumps is a frequent history in this disease. That mumps frequently damages the gonads is well known. The damaged gonads involve the remaining endocrines, the thyroid especially seems to be the particular gland disturbed. In our series endocrine disturbance was found in 95 females, or 70 per cent, in 28 males, or 31 per cent. These cases showed a definite endocrine involvement. The preponderance of females over males is to be expected, as I find endocrine disturbance in

general more frequent in the female.

Menstrual disturbances of all forms were frequent symptoms. Many of them showed

a leukorrhea of allergic origin. Sterility was not infrequent. The gastro-intestinal symptoms were not of an endocrine origin; for it is well known that the endocrine glands and the thyroid in particular will give rise to various gastro-intestinal symptoms. This was proven by the fact that specific endocrine therapy alone did not eradicate the condition. It was only when the allergic régime was instituted that positive and permanent results were obtained.

Comment.—One of the first signs of improvement is the rapid gain in weight of these patients under allergic treatment. The average allergic patient is more frequently underweight than overweight.

Gastro-intestinal allergy occurs at all ages.

SKIN TESTS

While practically every allergic patient responded with positive skin tests (the various allergins are too numerous to mention) in only about 50 per cent of the tests are the results dependable. By this I mean that frequently a skin test will be positive and the patient will be able to eat that food with impunity and conversely the skin test will be negative and the patient be poisoned by that particular food. Therefore the patient's own experience with a particular food forms the best and only guide to go by. The foods the writer found patients most sensitive to were the following in order of frequency: wheat, eggs, milk, cocoa, cabbage, orange, white potato, beans

and peas, veal and pork in the meats were especially allergic

BLOOD TESTS

It is an error to expect an eosinophilia in every case of allergy. By far the greater

to establish the diagnosis of allergy. The therapeutic tests were most valuable as a diagnostic aid. Where all previous efforts failed, and the anti-allergic treatment was followed by prompt relief of all symptoms,

number of patients do not show it neither during the active nor the quiescent stage. In our series there were positive eosinophilia from 4 to 22 per cent in 52 cases, 148 cases did not show eosinophilia.

The white blood count frequently showed a lymphocytosis, the total leukocyte count was, as a rule, normal, with few exceptions it showed a leukocytosis.

The red blood count frequently showed an anemia of the secondary type. In our series 65 patients showed an anemia of moderate severity while 137 showed no anemia. Can the anemia have as a basis the malnutrition and endocrine disturbance? Both are factors in this disease.

The gonorrhea complement fixation and Wassermann tests were performed upon 201 patients with only one single positive case for syphilis and 2 positive for gonorrhea. Evidently syphilis and gonorrhea are not factors in this disease.

GASTRIC ANALYSIS

With the exception of occult blood in 13 cases the rest of the findings were negative. As has been demonstrated elsewhere,⁸ capillary hemorrhage is a frequent finding in allergy.

Four patients showed blood in feces, other findings were negative.

URINE TESTS

Traces of albumin, a few red and white blood cells were frequent findings upon repeated examination. All other findings were negative.

Comment—In the exceptional case where pathology was found upon x-ray examination double precautions were taken

and where this was corroborated by history and other associated allergic conditions, skin tests, etc., x-ray was deemed superfluous.

DIFFERENTIAL DIAGNOSIS

In the differential diagnosis all points which have been brought out under history are of the greatest help. To differentiate from the inflammatory abdominal conditions we have, as a rule, absence of, or very slight, temperature, occasionally a

subnormal temperature may be present. Exactly the same rule holds good with the leukocyte count; as a rule, there is no elevation, or if present, it is slight, and there may be a leukopenia. Instead of a polymorphonucleosis there is, as a rule, a normal differential or a relative lymphocytosis. To depend upon the eosinophilia for a differential diagnosis is a mistake; it is too seldom found. Only a positive finding is of value; a negative finding has no value.

As a rule, other forms of allergy coexist, especially the cutaneous form, and very often if one looks for it, it may be objectively demonstrated at the time. As a rule, there are present not only symptoms referable to the digestive tract, but also symptoms referable to the nervous system, which frequently dominate and mask the picture. One can frequently reproduce the symptoms by exposure or ingestion of the suspected allergin, although the psychic character of the disease must be borne in mind. I have discussed elsewhere the differentiation from appendicitis.⁹ The absence of muscular rigidity is of great help. The negative cholecystography, the absence of duodenal drainage findings indicative of gallbladder disease points to the correct diagnosis. In peptic ulcers the x-ray is of great help. Intestinal obstruction, hypoadrenalism which may simulate it very closely, and even perforation of a viscus, as well as all the ones previously mentioned, may be differentiated by injecting hypodermically adrenalin which will clear it up, if of allergic origin. Allergic elimination diets promptly relieve all forms of gastro-intestinal allergy and exclude organic disease. Let allergy be not your first but your last diagnosis.

PROGNOSIS

When the allergin can be identified in the manner described, the prognosis is splendid. It is certainly wonderful to see a patient after a life-long suffering frequently unrelieved by operation, promptly and fully recover when the specific allergins are eliminated. To identify the latter is not always easy. Fatal cases have been reported. One hears very often about "outgrowing" this disease, but sees very little of it, although the allergin may change.

TREATMENT

PROPHYLAXIS.—These patients, as a rule, have an unstable nervous system, and the vagus sympathetic tone is easily disturbed. Therefore overexertion and ex-

cesses of all kinds are interdicted. Mental worries, aggravations, and depressions must be avoided as much as possible. The suspected allergin must be avoided. With foods this is very simple; substitutes can be easily found. When this is impossible or where pollens, dust, or other emanations which are impossible to eliminate exist, desensitization or immunization must be undertaken. It is wise to take general precautions which have been found of aid in other forms of allergy and to interdict sleeping on hair mattresses, feather pillows, overeating, exposure to dust, heat, cold, etc. I find that hydrotherapy is very useful, especially the warm sea-salt baths.

ACTIVE TREATMENT.—The principle is to eliminate the foods found responsible for the symptoms and to substitute others that do not give reactions. The anti-allergic elimination diet first proposed by Albert H. Rowe¹⁰ is of great help and robs the treatment of all its severity. This can be readily modified to suit the individual case. Another good way of starting treatment is to starve the patient for twenty-four hours then start in on one or two foods which you know agree with the patient and never give rise to symptoms. Add one new article of food every twenty-four to forty-eight hours. Eliminate the article of diet immediately upon the first sign of trouble. It is best to give rare foods and those which experience have proven give the smallest percentage of positive allergic reactions. Such foods the writer has found to be rice, corn and its products, egg plant, lettuce, spinach, endives, carrots, turnips, lemon, prunes, rhubarb, gelatine, molasses, sugar, coffee, parsley, salt, lamb, ripe olives, pineapples, mulberries, artichoke, sweet potato, tea, and figs. The foods which give rise to most allergic reactions the writer has found to be eggs, wheat, milk, cocoa, cabbage, orange, white potato, beans, and peas, in the order named. If a food is found to disagree it should not only be avoided; even the smallest quantity incorporated with another food should not be taken. As a rule, improvement will be noticed immediately or sometimes not before three or four days. After three or four months of abstaining from the specific allergin, if it is deemed desirable the patient may be desensitized by mouth against the specific food by beginning with the most minute quantity and daily gradually increasing the amount until a fairly large quantity can be

taken Occasionally one meets a patient who cannot tolerate the smallest particle of the offending allergin It is then advisable to omit the food entirely The various drug and biologic houses prepare food allergins for hypodermic injections, which yield very satisfactory results With these products, treatment according to given directions may be started at once

Feeding the patients peptone one hour before meals in the writer's hands has yielded no results Denaturization of food by prolonged heating gave poor results Very often severe vomiting will continue even after the specific allergin is eliminated and may become so severe that even water will not be tolerated by the stomach This is due to an acidosis, loss of chloride, or dehydration, or to their combination The usual treatment for this condition must be instituted before attempting anti-allergic treatment It is very gratifying to see how these undernourished patients gain markedly in weight as soon as the specific allergin is eliminated

The writer has found that tincture of belladonna in one-half glass of water fifteen minutes before meals, the dose steadily increased until physiological effects are obtained (beginning dryness in mouth, blurring of vision, etc.), and then maintained at that dose, is a decided help in these cases It is surprising what tremendous doses most of these cases will tolerate Auto-hemotherapy of 10 cc of whole blood gradually increased to 20 cc, given every other day for ten injections, is in some cases a help Viosterol is useful Other drugs in the order of usefulness are injections of 1 per cent flowers of sulphur in olive oil, luminal, iodides, dilute hydrochloric acid calcium gluconate, pilocarpine, arsenic, salicylates, vaccines, and pollens, wherever indicated In some cases diathermy and ultraviolet rays are of decided aid For the acute symptoms 10 to 15 minims of adrenalin by hypodermic is the drug of choice and repeated as frequently as indicated In severe cases the treatment should be that of shock, adrenalin, ephedrine, caffeine, camphor in oil, etc The endocrine glands by themselves do not cure the disease—they are of great help where indicated It is the elimination of specific allergin which is of the greatest help

Where other pathology coexists, as gall-bladder disease, appendicitis, peptic ulcer, etc., along with the specific treatment for the disease in question, the anti-allergic

regime should be incorporated The writer believes when a needless operation is performed on an allergic patient and this is followed for a variable length of time by improvement, the benefit derived is similar to the improvement following intravenous vaccine therapy mainly shock treatment, brought on by biologic insult

RESULTS OBTAINED—Males, splendid results in 74 doubtful in 11 Females, splendid results in 134, doubtful in 8 Results were held doubtful where observation was too short to justify conclusions of permanency of benefit

SUMMARY

1 Gastro intestinal allergy is rarely recognized, yet it is more frequent than asthma and hay fever combined

2 There are no pathognomonic signs or symptoms

3 The history is of the greatest help in the diagnosis and treatment

4 The disease is nearly always associated with other allergic manifestations especially of the skin, which is frequently mistaken for exanthema

5 Bleeding from mucous membranes and subcutaneously is often of allergic origin

6 Nose and sinus manifestations are frequently associated with allergy

7 The nervous symptoms often dominate the clinical picture

8 The vegetative nervous system frequently plays an important role

9 Endocrine glands are intimately associated with allergy

10 The occurrence and digestion of intra-gastric herpes are responsible for peptic ulcer

11 Skin tests are dependable in only 50 per cent of the cases

12 The gastric analysis and x ray examinations, as a rule, show negative findings

13 Eosinophilia is exceptionally present

14 Futile surgery is frequent

15 The elimination of the specific allergins yields gratifying results

Symposium on Syphilis

PREVENTION OF CONGENITAL SYPHILIS

JACOB A. GOLDBERG, PH.D.

Secretary, Social Hygiene Committee, New York Tuberculosis and Health Association

INTRODUCTION

The tragedy of syphilis is most apparent in the case of children whom we denominate as congenital syphilitics and for whose stigma several groups in the community share the responsibility. Various studies have been made relative to the incidence of prenatal syphilis as well as of congenital syphilis, but there are still a number of matters that need to be clarified on the basis of additional data. Recent figures, obtained from twenty-six hospitals in New York City in which routine blood tests are done on all prenatal clinic cases, indicate a range of from less than 1 per cent to 19 per cent of prenatal cases with positive serological findings. The higher figures were found in clinics which serve a comparatively large percentage of Negro women. No comparable figures are at present available to any extent relating to the incidence of congenital syphilis. Stokes claims that congenital syphilis is present in from 3 to 4 per cent of the living children of our city populations. Studies in Boston, St. Louis, and elsewhere seem to agree with this estimate, though higher figures have been indicated for Negro children in the South. It is quite apparent that the paucity of reliable data and the failure adequately to disseminate, among lay and professional groups, such information as is available may, in part at least, be responsible for the lack of vigorous action by the medical profession and others in taking measures to stem constantly recurring cases of congenital syphilis.

The prevention of congenital syphilis is necessarily part and parcel of the problem of adequate treatment of cases of prenatal syphilis. While there is no cavil about this causal relationship, there is, nevertheless, much that remains undone in medical institutions, and possibly among private practitioners as well, to check syphilis among pregnant women, so that their children might be born free of the parental taint.

In order to obtain an appraisal of the present situation insofar as the treatment of prenatal cases of syphilis is concerned, as well as to determine what are common procedures in such treatment, a study was recently instituted of the records of seven hospitals in New York City and covering 653 cases of prenatal syphilis. In this study, in which the hospitals are referred to by letter, information was sought relating to the month of pregnancy on admission to the clinic; blood test findings; number of treatments given; blood retests and findings; date of delivery and where delivered; condition of mother and of baby after delivery; accidents of pregnancy; prematurity and stillbirths; cause of death of mother or child; age at death; condition upon discharge from hospital, both of mother and child; result of blood test on child; diagnosis on postpartum visits to clinic and treatment instituted; visits of baby to clinic, including condition; record of previous pregnancies and results; findings on serological tests of other children in same families; and findings on such tests of husbands.

The distribution of cases by color shows a disproportionate number of Negro women registered among those studied. Comparative figures which are available indicate that the prevalence of syphilis, as measured by a positive serological reaction, among Negro pregnant women who attend prenatal clinics in New York City, is at least three times as high as that among white women attending similar clinics; and fifteen or more times as high as that among women in similar clinics in certain areas of the City. This situation points to one of the unfilled needs in the community health program.

It may not be amiss to indicate at this point that the incompleteness of clinic records seriously interfered with the comprehensiveness of the present study; and it warrants the suggestion that those in positions of responsibility would render a

real service by seeing to it that the records of prenatal syphilitics are carefully and completely filled out

is markedly overcrowded and understaffed in several departments

The number of treatments for prenatal

TABLE I—AGE DISTRIBUTION

Age	A	B	C	D	E	F	G	Total	P C
15-19 years	18	16	6	5	31	3	7	86	13.4
20-24 years	60	30	26	15	84	18	12	245	38.2
25-29 years	44	29	13	8	57	7	5	165	25.7
30-34 years	30	7	7	4	31	8	6	93	14.5

No record	1	3	2		5	1		12	
Totals	168	97	62	33	223	40	30	653	100.0

Table I notes that 13.4 per cent of the women were from 15 to 19 years of age, 38.2 per cent between 20 and 24 years of age, 25.7 per cent from 25 to 29 years of age, 14.5 per cent between 30 and 34 years, and 7.5 per cent between 35 and 39 years. These percentages are comparable to those pertaining in most areas of this country, though percentages for Negro women alone show a higher figure in the earlier age groups.

syphilis will naturally be influenced by the month of pregnancy in which the patient reports, and the regularity with which she returns for treatment. The end results will be further affected by the adequacy of the treatment given. Aside from the need of beginning treatment early in pregnancy, it has been empirically accepted that the woman receiving adequate treatment has a good chance of having a healthy child. In one of the hospitals studied, the

TABLE II—MONTH OF PREGNANCY ON ADMISSION

No record	2	3	2	4	4	2	2	19	
Totals	168	97	62	33	223	40	30	653	100.0

It has been an axiom for some time that the earlier in the course of the pregnancy the antisyphilitic treatment is begun, the better the outlook for both mother and child. It has further been shown that for the treatment to be really effective, it must be started before the fifth month. From Table II it will be noted that, for the group as a whole, only 22.5 per cent of the patients were put under treatment before the fifth month, whereas the several institutions show a marked variation in their records. Hospital A, with 37.5 per cent under treatment before the fifth month of pregnancy, has a high standard of service, a good social service department, and the chiefs of service are known to take a special interest in the problems of prenatal and congenital syphilis. On the other hand, Hospital E, with only 7.8 per cent of the patients registered before the fifth month,

standard procedure is to give 9 injections of neosalvarsan, and if the Wassermann test remains positive, the treatment is continued. Of the patients reported upon in this study, 36.7 per cent received 5 treatments or less, and 56.3 per cent 9 treatments or less. The institution in which the treatments per patient were fewest in number was that in which facilities are most inadequate, with insufficient medical, nursing, and social service personnel.

The importance of repeated serological tests, particularly in the case of prenatal syphilitics, is generally recognized. If an appraisal is to be made on the basis of the records studied, it would appear that such tests were not repeated, for whatever reasons, in 35.6, or 55 per cent, of the cases. The variation between the seven institutions was extremely marked. Hospital A reported 151 out of 168 cases, or

90 per cent, with tests repeated, while the records of Hospital *G* indicated only one case out of 30 retested. The other five hospitals had a rather low record of achievement. Incidentally, of those women

is not given adequate attention. Hospital *A*, for instance, was able to report that out of the surviving children, 114, or 71.7 per cent, were brought to the clinic one or more times; Hospital *E* reported that all

TABLE III.—PREVIOUS PREGNANCIES

Totals.....	168	97	62	33	223	40	30	653	100.0

who were given a repeated test, 55 per cent were reported as either three plus or four plus, thus emphasizing the need for a check on the treatment administered.

In attempting to tabulate the accidents of pregnancy, some difficulty was encountered, as the records were incomplete in 182, or 28 per cent, of the cases. No recorded deaths of mothers occurred, though there were 6 cesarian deliveries; of the infants, there were 20 stillbirths, 13

surviving children were returned one or more times; whereas in Hospitals *B* and *D* there were no further examinations or treatments; and in Hospital *G* only one child out of 30 was recorded as having returned for observation and treatment. The failure to follow up and treat such children is indeed a matter of serious concern.

In analyzing the history of previous pregnancies in this series of 653 women,

TABLE IV.—RESULT OF SEROLOGICAL EXAMINATION OF HUSBAND

Blood test findings	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>E</i>	<i>F</i>	<i>G</i>	Total	P. C.
Negative	61	2	29	..	45	1	..	138	71.3
Positive (2)	4	4	2.1
(3)	1	..	4	..	7	12	6.4

Doubtful	1	..	1	2	1.0
No record	87	95	23	33	154	39	30	461
Totals.....	168	97	62	33	223	40	30	653	100.0

premature births, 6 died shortly after birth, and 6 were reported as macerated. The rate for stillbirths, which was about 6 per cent, is comparable to that for a five-year period in the Borough of Manhattan. However, if the nonviable fetuses are included in the total picture, the percentage of loss mounts up much higher. It may be fair to assume that syphilis contributed a share to the increase.

Postpartum observation and treatment would necessarily be assumed to be highly important in the present series of cases, yet 270, or 42.8 per cent, did not return at all, and 147, or 22.5 per cent, came only once. The records at the seven hospitals varied widely in the number of patients who returned for further treatment.

The desirability of follow-up service and treatment for children born of syphilitic mothers hardly needs emphasis. Results, as indicated by a study of the records, would apparently warrant the conclusion that in some hospitals, at least, this matter

the records were found incomplete in 43 instances, and 181 were reported with no previous pregnancy. On the basis of the 429 women who had been pregnant one or more times, 78, or 18.2 per cent, gave a history of one or more miscarriages, and 85, or 19.8 per cent, one or more stillbirths; and a few gave histories of both. Thus, of the women who had prior pregnancies, 38 per cent at some time did not give birth to living children. If to this 38 per cent is added the loss in the pregnancies under study, a record of 46.6 per cent of the women in this series is noted with so-called accidents of pregnancy. This is indeed a high figure. The question that naturally arises is, how much of this loss is due directly to syphilis and how much to other causes. The presumption is undoubtedly warranted that pregnant women with syphilis are highly prone to accidents of pregnancy, and that, in addition, a fair proportion of their living children are apt to be congenital syphilitics.

Plans for the control of syphilis and the prevention of congenital syphilis would presume ordinary care in checking up the incidence of syphilis among living children, as well as among the husbands of syphilitic pregnant women. And yet, serological tests were made on children in only 84 of the families, and on but 192, or 29.5 per cent of the husbands.

The difficulties inherent in obtaining the necessary cooperation for the making of serological tests of children and husbands are well recognized. However, it should be noted that these presumed difficulties were apparently more real in some hospitals than in others. In Hospitals *B*, *D*, and *G* none of the living children of syphilitic mothers were examined. Likewise, in Hospitals *B*, *D*, *F*, and *G*, only one or two, or none of the husbands of these women were examined. It would, therefore, appear to be somewhat dependent upon institutional policy and procedure as to whether or not these necessary examinations are made.

SUMMARY

The preceding data are in necessarily abbreviated form, with much of the statistical information omitted. The more important findings in this study of 653 cases of prenatal syphilis in seven prenatal clinics in New York City are as follows:

(1) Only 22.5 per cent of these cases were put under treatment before the fifth month of pregnancy, though in one hospital a 37.5-per cent record was achieved.

(2) The antisymphilitic treatments administered to these women were possibly too few in number, as 36.7 per cent were given 5 treatments or less, and 56.3 per cent 9 treatments or less.

(3) In many instances blood tests were

not repeated, and when such retests were made, three-plus and four-plus findings were recorded in 169 instances, or 55 per cent; and negative in 85, or 28 per cent.

(4) Of the cases in which complete records were available, there were 426 normal births and 45 losses, including 20 stillbirths, 13 premature, 6 deaths immediately after birth, and 6 macerated cases.

(5) There were 304 recorded blood tests of the newly born children, and of these 242 gave negative reactions, and 51, or 16.7 per cent, strongly positive reactions. The value of such tests made shortly after birth has been seriously questioned.

(6) The record of postpartum visits to hospitals in which confinement took place shows that 42.8 per cent of the women failed to return and 22.5 per cent made only one visit.

(7) The record of visits of children born of these syphilitic mothers is comparatively high in one hospital with 71.7 per cent returning for at least one visit, and very low in other institutions studied.

(8) The records indicate that 46.6 per cent of the women studied had passed through a nonfruitful pregnancy; 38 per cent related to a prior pregnancy; and 8.6 per cent to the current pregnancies studied.

(9) Few living children of these mothers were given blood tests for syphilis.

(10) Only 192 husbands were given blood tests, and of these, 28.0 per cent were reported as positive for syphilis.

(11) More consideration as to procedures in caring for prenatal cases with syphilis would undoubtedly result in the saving of lives, in reducing various manifestations of late syphilis, and in preventing the blight of congenital syphilis from affecting many children in the community.

DIAGNOSIS, IMPORTANCE, AND TREATMENT OF EARLY SYPHILIS

GEORGE M. MACKEE, M.D.

New York, N. Y.

By early syphilis is meant, roughly, the first two or three years of the disease; in other words, inoculation, first incubation period, the chancre stage or primary syphilis, the second incubation period, and finally, secondary syphilis. Early syphilis is important for two reasons: First, it is

during this period that the specific organisms are disseminated throughout the system and unless destroyed while accessible to lethal remedies they may produce inaccessible foci in the cerebrospinal system, the cardiovascular system, and various viscera which may subsequently give rise

to the serious lesions of late syphilis. It is in early syphilis, therefore, that one has the best opportunity to effect a cure and to prevent disastrous late results such as paresis, tabes, aneurism, and other well-known conditions. The incidence of syphilis is greatest in the third decade. The damaging manifestations of the disease are most common in the fifth and sixth decades. The diagnosis and adequate treatment of early syphilis will substantially reduce the morbidity and mortality of middle age.

The second reason for the importance of early syphilis is that many of the lesions are contagious. Unless the disease is quickly controlled the patient is a menace to society.

Inoculation usually occurs in the skin or in the orificial mucous membranes. The spirochetes remain in the immediate area only a few hours. Within a few days, even within twenty-four hours, the organisms may reach the lymphatics, blood, and viscera. Therefore, syphilis must be considered a systemic infection practically from the time of inoculation, and local prophylactic measures are useless unless applied immediately after inoculation. The chancre, which is the first clinical evidence of the disease, develops at the site of inoculation in from twelve days to about three weeks. Successful and unsuccessful attempts have been made to quickly cure the disease in humans during the early primary incubation period; that is, a few days after inoculation, by intensive treatment with arsphenamine. This method has not yet been standardized nor evaluated. In selected cases it seems justifiable. But when tried, the patient should be kept under observation for a year after one or two courses of intravenous arsphenamine injections.

When inoculation occurs in the usual manner; that is, in the skin or orificial mucosa, there is, as a rule, an orderly sequence of events. First, there is the primary incubation period already mentioned. Then the chancre develops at the site of inoculation. This is accompanied by a painless, palpable lymphatic gland in the immediate neighborhood. In a few weeks this is followed by slight constitutional symptoms, a positive blood serology, a roseola and other cutaneous manifestations of secondary syphilis. Exceptions are numerous and are of importance because they interfere with diagnosis.

Instead of the usual cutaneous inocula-

tion, the spirochetes may enter the blood stream directly, as occasionally occurs during blood transfusions. In such event the orderly sequence just referred to may not occur. The first manifestation of the disease may be a positive blood Wassermann reaction, or a macular exanthem, or an eruption more characteristic of the later secondary period, or even more definitely precocious eruptions. Another exception to the orderly sequence of events is seen in congenital syphilis of early type. Other exceptions are caused by inadequate treatment, variations in acquired immunity, and so on.

The typical genital chancre, with its hard induration, flat, slightly ulcerated surface, and rather slow evolution, is easily differentiated from other conditions. A typical primary lesions are more difficult to diagnose clinically. At one extreme the lesion may be so small that suspicion of its true nature is not aroused. At the other extreme, perhaps because of mixed infection, the lesion may consist of a large, deep ulcer with little or no induration, accompanied by a large, painful lymph node. Again, the initial lesion may be hidden in the vagina, urethra, throat, rectum, etc., and hence overlooked or incorrectly diagnosed.

The diagnosis of the chancre must be unequivocal. The clinical diagnosis must be confirmed by the microscope. The *Spirochaeta pallida* must be differentiated from other spiral organisms. It is often necessary to repeat the examination several times after applying a continuous saline wet dressing to the lesion for a day or two, before the organisms can be demonstrated. Serum should be obtained from within the lesion. Occasionally it is advisable to obtain serum from the satellite gland. At times, especially when the suspected lesion has been in existence for two or more weeks, it may be advisable to excise the enlarged lymph node, or the chancre, for histological examination. The point to be emphasized is that every accepted method should be used to verify or refute the suspicion of primary syphilis.

The blood serology should be obtained as soon as the patient comes under observation. It should be negative when the chancre first appears. It will be positive usually within two or three weeks subsequent to the development of the primary lesion, although it may be delayed for several weeks longer. When the diagnosis

has been missed in the primary stage, one should, in the writer's opinion, wait for a four-plus Wassermann reaction, which usually occurs before eruptions develop, rather than depend entirely on the less conventional serological tests, or on cutaneous manifestations. Also, it is advisable to send specimens of blood to two laboratories simultaneously.

While syphilis is constitutional from the beginning, the so-called secondary phase of the disease begins a few weeks after the appearance of the chancre—after the second incubation period. The first detectable evidence of secondary syphilis may be malaise, anemia and general adenitis, or a positive blood serology, or an eruption, or a combination of these features. A positive blood serology, in untreated cases, is almost certain to occur and is reasonably dependable. The other features, alone, are not so dependable because they may not occur, they may be overlooked, or they may be mistaken for some other condition. Therefore, in untreated cases, a four-plus positive blood Wassermann reaction is deemed essential for the absolutely certain diagnosis of untreated early secondary syphilis, unless there are lesions such as mucous patches or moist papules in which *Spirochaeta pallida* can be demonstrated.

Secondary cutaneous syphilis has certain fairly definite and well-known characteristics. When the eruption occurs very early—from four to six weeks after the appearance of the chancre—it consists usually of a generalized macular exanthem, often with involvement of the palms and soles, and perhaps accompanied by concomitants such as the constitutional symptoms previously mentioned, mucous patches on the orificial membranes, sore throat, moist papules in the flexures, and split papules at the buccal commissures.

Maculopapular eruptions, large and small papular eruptions, mottled alopecia, and syphilitic leukoderma usually represent a later period than is indicated by the very early macular exanthem. In the absence of precocious syphilis, squamous eruptions and discoid eruptions indicate a still later stage. Recurrent eruptions (recedives) occur occasionally in the second and third years and even later. They may be macular or they may consist of a mixture of macules, papules, squamous lesions, etc. The early cutaneous syphilides are not destructive and they tend toward universal distribution. They are not grouped or

configurate. Later, there is a tendency toward general rather than universal distribution, and still later there is grouping, configuration, and localization. These various eruption characteristics make it possible to obtain some idea of the duration of the disease.

When discussing the treatment of early syphilis one should keep in mind certain important fundamentals. The diagnosis should be made as early as possible, and it must be beyond dispute. Treatment should be begun at once, and while it should be modern and adequate, it should not kill or permanently injure the patient. The modern treatment of syphilis is dangerous when unintelligently or injudiciously administered. Adequate treatment includes selection of drugs and dosage, time intervals between treatments and courses, the number of courses, the period of time over which treatment extends, a careful follow-through, physical and laboratory check-up, and so on. Hardly any two syphilologists agree on therapeutic details but there is general accord relative to therapeutic principles. Time permits only a general therapeutic outline with enumeration of the principal indications and contra-indications. It is impossible here to discuss technic, various drugs, criteria of cure, syphilis and marriage, or even to elucidate dogmatic statements.

In the early primary stage with positive dark-field and negative blood, the author recommends 3 intravenous injections of neoarsphenamine the first week. The first dose is 0.3 gm. The next 2 injections consist of 0.45 gm. This is followed by 7 neoarsphenamine injections, 0.45 gm. each, and 7 intramuscular injections of bismuth, at weekly intervals. After a rest interval of three weeks a second course of weekly injections of both drugs, at the same dosage, is given. The two drugs are not given on the same day. A total of four courses are given over a period of a year with rest intervals of approximately one month. The patient should then be kept under observation for a year or two.

In the case of a dark-field positive chancre plus a positive blood serology but no other manifestations, the treatment for the first year is the same as that outlined, except that the first injection of neoarsphenamine is 0.2 gm., and also, the treatment is continued during the second year. During the second year three courses of combined treatment are given. If then the

patient is negative physically and has a negative cerebrospinal and provocative blood serology, treatment is discontinued, but a check-up is requested each year for several years.

When the patient is in the frank secondary period at the time treatment is begun, *i.e.*, the chancre has healed, the blood serology is positive, and there are, perhaps, cutaneous or other clinical manifestations, the treatment is less intensive at the beginning and is continued over a much longer period. In order to avoid the possibility of a dangerous Herxheimer reaction, the author prefers to begin with three or four doses of insoluble bismuth administered intramuscularly at intervals of one week (bismudol, for instance: first injection 1 gr., thereafter 3 gr.). These injections are continued for fourteen weeks. Neoarsphenamine is begun in the third or fourth week, the first injection being 0.2 gm. Thereafter 0.45 gm. are given each week for a total of 10 injections. The course, therefore, consists of 10 neoarsphenamine and 14 bismuth injections. Six such courses are given during the first two years with rest intervals ranging from one to two months. After the second year the management of the case varies according to conditions. Courses as above outlined may be necessary during the next few years. Even when the patient seems to be cured at the end of the second year, it is advisable to give one course of arsphenamine

and two courses of bismuth during the third year, and two courses of bismuth in both the fourth and fifth years. In a Wassermann-fast case, it may be advisable to try other drugs including iodine and perhaps less conventional methods such as protein therapy. In all cases the general health must receive attention. The cerebrospinal serology is determined toward the end of the first year. The usual criteria of cure are fulfilled before treatment is discontinued, thereafter the patient is examined yearly.

This therapeutic outline is routine and must be modified in accordance with various indications and contra-indications. When one arsenical is not well borne perhaps another will be tolerated. To some extent dosage is governed by age, sex, weight, and especially by toleration. When intravenous injections are impossible, bismarsen may be administered intramuscularly. When the arsenicals are not tolerated, good results may be obtained with insoluble and soluble salts of bismuth or mercury or both.

In conclusion, it may be said that the successful management of syphilis requires a comprehensive knowledge of the disease and an equal knowledge of all established methods of treatment. It is possible for most physicians, especially those in large medical centers such as New York City, to acquire an excellent practical knowledge of syphilis and its management.

200 WEST 59TH STREET.

THE MIDDLE-AGED AND ELDERLY SYPHILITIC: SPECIAL PROBLEMS IN DIAGNOSIS AND TREATMENT

A. BENSON CANNON, M.D.

Associate Professor, Department of Dermatology, College of Physicians and Surgeons, New York, N. Y.

Most of us engaged in hospital and clinic practice are surprised at the frequency with which the routine blood examinations disclose a strongly positive Wassermann reaction. Many of these cases having positive Wassermann reactions have been invalids or semi-invalids for years, oftentimes with such obscure symptoms that it has never occurred to the attending physician to make a Wassermann test (Fig. 1).

VARIETY OF SYMPTOMS

Some patients may present evidences of

a severe secondary anemia; others complain only of exhaustion and loss of initiative. Some may suffer with late afternoon headaches, or may show symptoms of a cardiovascular disease, such as aortitis, aneurysm, myocarditis, heart block, arterial spasms, hypo- or hypertension. Others have symptoms referable to the nervous system, such as a nervous breakdown, neuralgia, or rheumatic pains. Sore muscles, fainting spells, transient weakness, or even paralysis are not uncommon. Sometimes the patients have ocular palsies

or other visual disturbances. Again we encounter gastro-intestinal symptoms suggestive of duodenal or gastric ulcer, and still again, such visceral diseases as hepatitis, diabetes, or nephritis of syphilitic origin. It is this extraordinary variety of symptoms one finds resulting from syphilitic infection which makes this disease so interesting to us all, and which should keep us constantly on the alert in its detection.

ROUTINE WASSERMANN'S

Referring again to the routine blood examination, it might be of interest to recall that statistics from various private and semiprivate institutions show that from 2 to 12 per cent of the cases admitted to these hospitals have strongly positive Wassermann reactions. Zimmermann found that from a group of 500 tuberculous patients, 2 per cent had undiagnosed syphilis. Schroder, in a similar group found 4 per cent, Coster 2 per cent, and Landsberg 3.2 per cent. In the Vienna General Hospital, 12.12 per cent of more than 7,000 patients were found to be syphilitic. In the Presbyterian Hospital in New York for the year 1931, there were 3.1 per cent; and in our City Hospital, of the 23,279 patients admitted in 1930, 1931, and 1932, 2,115, or about 10 in every hundred had syphilis. Recent routine Wassermann tests on students from three of the professional schools of the University of Minnesota—medicine, dentistry, and education—over a period of two years, revealed 10 students with strongly positive reactions. Considering the above statistics, the wisdom of the routine Wassermann test seems undeniable.

INTERPRETATION OF THE WASSERMANN TEST

The diagnostic value of the strongly positive Wassermann test is recognized, I dare say, by all of us. With the exclusion of yaws, we can say with a fair degree of assurance that a carefully controlled and repeated four-plus Wassermann reaction means that the patient has syphilis. Our difficulty in making a diagnosis begins when we obtain a moderately positive Wassermann from the serum of a patient who has no symptoms or physical signs of syphilis. It is often necessary to repeat the Wassermann many times, and to supplement this by other tests, such as the Kahn and the Kline, and perhaps

the Meinicke tests, over a period of several weeks. Again, we may give a provocative arsphenamine injection, this is particularly valuable in patients with gummatous lesions, the Wassermann often becoming strongly positive after the injection.

The following case illustrates the importance of carefully controlling the Wassermann tests, especially where a positive report is given with serum obtained in the course of a routine examination and where

Fig 1—Multiple gumma of eleven years' duration following injury and operation. Wassermann test had never been made.

there is neither a history of infection, symptoms nor physical signs of syphilis.

A young woman aged 19, was referred to the author on November 19, 1933, for anti-syphilitic treatment.

She had been admitted to a hospital for a cold and sinus infection and a routine Kline test done there had been reported four plus. A second Kline test done four days later was also four plus but the Kolmer test was negative. Three specimens of blood serum sent to the Board of Health, were all reported strongly positive, four plus.

The patient's family history was negative, her father, mother, two older sisters and one brother, all had negative Wassermans. The young woman denied all symptoms of venereal infection, she looked to be unusually strong and healthy and her physical and neurological examinations showed nothing abnormal.

Our laboratory report was two plus cholesterin; negative alcoholic; two plus Kahn; four plus Kline. We repeated the tests fourteen days later and every one of them was negative.

We then gave a provocative arsphenamine injection following which we tested the patient's blood eight times over a period of a month and all the reports were negative—Wasserman, Kline, and Kahn. We sent one specimen to the Board of Health, one to Columbia University, and one to Dr. Kolmer in Philadelphia; the latter two were reported negative; the report from the Board of Health was plus minus.

TREATMENT

Treatment of late syphilis is a different problem from that of early syphilis. Instead of having the young, robust,

Fig 2—Gumma of lip of three months' duration and interstitial glossitis, leukoplakia, and atrophy of tongue. Lesion on lip had been diagnosed and treated at one of the local hospitals. His blood Wassermann test had never been taken.

healthy individuals usually seen with early syphilis, we have patients in middle or advanced age, often showing evidences of senility. Their syphilitic infection is often complicated by other and more serious conditions of health. These tertiary cases are poor risks; and inasmuch as they are not usually infectious, we do not have to consider the problem of sterilization by intensive treatment. Furthermore, late syphilis does not offer the inducement of a negative Wassermann reaction in a short period of time; if a negative blood test is ever obtained, it requires at least two to five years, and there is still much uncertainty as to the significance of a negative Wassermann reaction in this stage of the disease. Many years ago, long before

we had the benefit of the Wassermann test in establishing a diagnosis of syphilis, Dr. Pratt, a general practitioner in New Orleans, used to say that mercury and iodide in the form of mixed treatment was a most excellent tonic for people suffering with many obscure chronic ailments. We might venture to guess that those who showed the most beneficial results from such a tonic were syphilitics.

Treatment of Elderly Syphilitics.—In the case of the elderly syphilitic, then, or one in late middle age, our foremost consideration is to relieve the patient's symptoms with the least amount of medication and minimum discomfort to him. At the Vanderbilt Clinic, it is a rule not to give arsphenamine to an individual over fifty years of age unless specifically indicated, and then only in small doses and at weekly intervals, the patient remaining under careful observation. When the syphilitic symptoms have been relieved, we depend on alternate courses of mercury and bismuth, supplemented by potassium iodide or mixed treatment, the latter consisting of

Hydrarg. chlor. corros. gr. iii

Iodid. Potass.

Elix. Lacto Pep.

M-Sig. Teaspoonful in glass of water
15-30 minutes after meals.

Importance of Encouraging the Syphilitic.—In many such cases, it is necessary constantly to encourage and to reassure the patient. A positive Wassermann reaction in itself or a positive Wassermann reaction in a symptom-free patient, does not show necessarily that he is in a dangerous condition, or that the syphilis will prove fatal for him. The author could point out a number of men 65 to 84 years old with four-plus Wassermann reactions and with a history of syphilis of 40 to 45 years' duration—men who have never had any treatment. They have in many instances enjoyed excellent health and have had active and successful careers.

Treatment of Patients between 40 and 50 Years.—When it comes to the tertiary syphilitics between 40 and 50 years of age, it is always difficult to know how actively one should treat, especially if the patient has a four-plus Wassermann reaction without symptoms. The author has come to believe that where the patient's expectancy of life is from 20 to 35 more years, his physician should make a special effort to

obtain a negative Wassermann by treating him continuously over a period of several years with alternate courses of arsphenamine, mercury, or bismuth and mixed treatment, as described above. Our Clinic plan usually provides for such a case 15 weekly injections of mercury or bismuth with iodides by mouth, this treatment to be followed by 10 weekly injections of old arsphenamine. Two or three such alternate courses of arsphenamine and mercury are given, after which the patient is placed on a 5 to 6 months' rest. During this time he is to take mixed treatment. Fol-

remedy for syphilis, yet not infrequently it produces alarming symptoms of poisoning in one form or another. Most of us have seen tragic results following the administration of arsphenamine or one of the heavy metals. Ill effects may, and all too often do, occur, even in young and otherwise healthy subjects and of course there is all the greater need for caution in cases of the type under consideration here where to the risk inherent in the medication there is added the handicap of age and its complications. These patients are particularly susceptible to jaundice

Fig 3—Marked destruction of nose and lip from gumma of nine months duration. Was treated by private physician for several months with salves. Wassermann test had not been made.

lowing the rest period, he is given a course of 15 bismuth injections, then 10 more weekly doses of arsphenamine, and again a 6 months' rest with mixed treatment. Frequent physical examinations, Wassermann tests, urinalyses, and blood counts are made during the period of observation, of course, the spinal fluid is tested

SYMPTOMS OF POISONING DURING TREATMENT

It is unfortunate that the greater number of our most valuable and effective drugs are poisonous and must be prescribed with caution. Arsphenamine is our most potent

Fig 4—Multiple gumma of scalp and perioosteum of four years duration. Wassermann test had never been made.

dermatitis, and neuritis. For this reason it is important to make frequent tests of blood and urine, in addition to careful and repeated physical examinations, as long as the patient remains under treatment.

Laboratory Tests to Detect Intolerance to the Drugs—The first course of treatment should always be preceded and usually followed, by a blood chemistry examination. The icteric index and the Van den Bergh test are valuable guides to the tolerance of the liver for the drug, an icteric index of 15 or above should be interpreted as a warning to discontinue arsphenamine and give sodium or calcium 30—Medical Journal—Overmatter, 5935 thiosulphate until the reading reverts to 10 or below. It is also advisable to examine the blood and urine for arsenic before beginning a course of arsphenamine.

injections, and to repeat these examinations several times during the course. Any patient whose blood reveals the presence of more than 0.09 mg. of arsenic per 100 gm. of dried specimen before beginning arsphenamine medication should be watched with especial care, for the chances are that he is getting arsenic from some outside source, such as foods, "tonics," etc., and it is a question whether his powers of elimination will be able to keep pace with the increased burden. In patients who are tolerating their arsphenamine without any untoward symptoms, a finding of 0.08 or 0.09 mg. of arsenic in the blood is not a cause for alarm, but if the figure rises much beyond this, it usually indicates undue retention of arsenic in the system and calls for at least a temporary discontinuance of the drug. The same holds true of urine findings.

Careful Technic.—Besides the precautions of physical and laboratory examinations already outlined, the writer cannot too strongly emphasize the necessity for a

careful technic of injection. Most syphilologists will state that while they have had cases of arsphenamine dermatitis appear in their hospitals and clinics, they have never had a generalized exfoliative dermatitis in their private practice. An arsphenamine dermatitis nearly always means either a break, somewhere, in the technic, or else the administration of too large or too frequent doses of the drug, or both. Just how many cases owe their origin to a paravenous infiltration will probably never be known, but many have been definitely traced to such mishaps.

As we grow in experience, we become more and more cautious in our use of the antisyphilitic drugs, even in the most vigorous subjects; and certainly no single class of patients presents such a challenge to the general knowledge and discrimination of the physician as do the latent and tertiary syphilitics. The author knows of no group deserving more careful preliminary study and many-sided follow-ups than these.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The Eastern Section of the Congress has arranged for a joint meeting with the New York Physical Therapy Society and the Pennsylvania Physical Therapy Society to take place on April 7, 1934, at the Medical Center in New York City. The meeting will have a morning session, a luncheon and an afternoon session. Clinical demonstrations have been combined with papers by speakers of note.

Dr. William H. Schmidt of Jefferson Medical School will talk on *Fever Therapy*.

Dr. George Miller MacKee of Columbia University on *Physical Therapy in Dermatology*;

Dr. Leroy W. Hubbard of Georgia Warm Springs Foundation on *Muscle Training and Re-education Exercises in the Treatment of Anterior Poliomyelitis*;

Dr. Max Thorek of the Cook County Graduate School of Medicine in Chicago on *An Electro-surgical Method for Obliteration of the Gall-bladder*;

Dr. Robert H. Kennedy of the Beeckman Street Hospital in New York City on *Physical Therapy in the Treatment of Fractures*;

Dr. Earl R. Carlson of the Neurological Institute in New York City on *The Neurological Aspect and Treatment of Birth Injuries*.

The Tugwell bill at Washington is said to be meeting stormy weather. The patent medicine and cosmetics industries are up in arms against its provisions, which threaten to ban their most effective, if least truthful, advertising claims.

Congressman Sirovich, of New York, has introduced a bill to regulate interstate traffic in food, drugs, nonalcoholic or nonintoxicating drinks, and cosmetics.

French doctors have confirmed the old belief that bee stings are good for rheumatism. They were themselves skeptical at first, we read in the *Journal of the A. M. A.*, but twenty experiments convinced them. They placed the bees in a cupping glass on a sheet of paper, then applied it to the affected spot and withdrew the paper. Thirty bees stinging the patient at one "sitting," every three days, is declared adequate. The treatment often takes two months. A solu-

tion of bee venom, it seems, can be used hypodermically with the same results. This remedy is very ancient, being mentioned by Hippocrates.

Much interest is being manifested in medical circles in the amendments now pending in Congress to relax the present federal birth-control laws. Popularly styled the "Doctors Only" bills, they would amend the existing federal restrictions so as to legalize the sending or receiving of contraceptive information, instruments and medicines between physicians and their patients, medical colleges and hospitals and from physician supply houses and manufacturers. Under the present statutes, penalties of heavy fines and imprisonment may be inflicted for transporting any article intended for the prevention of conception or for receiving for distribution to others any such article that has been transported interstate or by the government mails.

ANNUAL MEETING

of the

Medical Society of the State of New York

AT UTICA
MAY 14, 15, and 16

The Hotel Utica will be General Headquarters The Hotel Martin will house the Scientific and Commercial Exhibits, also the General Sessions The Section meetings will be held in various outside places

Please read your program carefully, find the exact location of each Section and make out your schedule so that you will not lose time in going from one place to another Check off the papers you wish to hear and, if possible, come prepared to join in the discussion

There will be several Scientific Exhibits of interest to the general and special practitioners The Commercial Exhibit will, as usual, be worth your time Investigate the newer medical and surgical appliances Competent demonstrators will be in attendance at both exhibits

Make your hotel reservations early, verify your room and secure the accommodation that you desire The Local Arrangements are in charge of Dr Andrew P Sloan, who extends a whole hearted welcome to all members of the Society After your arrival in Utica he and his efficient committee will attend to your physical comforts

A special entertainment is planned for Tuesday evening, the details will appear in the final program which you will receive several days before you leave for Utica

Be sure to make your hotel reservations in advance and plan to stay in Utica for the entire session

FOR THE LADIES

A special invitation is extended to the ladies of the profession, the wives and daughters of physicians It has been a long trying winter Your husband needs the relaxation and the mental stimulation of contact with his fellow practitioners You deserve a change The ideal way to receive mutual benefit is for you to come with him to Utica

Begin to make your arrangements to have an enjoyable vacation at the time of the Annual Meeting of the State Society Note particularly the days, May 14th, 15th and 16th Leave home on Sunday so as to arrive in Utica, Sunday evening, or at the latest Monday morning Enjoy the trip to and from Utica and after your days in that city you will return to your work refreshed and rejuvenated

Scientific Program

All Meetings Will Be Held By Daylight Saving Time

GENERAL SESSIONS

Place of Meeting—Hotel Martin, Ballroom, Second Floor

Tuesday, May 15th, at 2:00 P. M.

SYMPOSIUM: The Hormones Which Influence Growth and Reproduction.

1. "The Pituitary Sex Hormones", Philip E. Smith, Ph.D., New York (Invited Guest)
2. "Nature and Action of Ovarian Therapy, Including the Corpus Luteum, from the Laboratory Standpoint", George W. Corner, M.D., Rochester (Invited Guest)
3. "The Present Status of the Female Sex Hormone from the Clinical Standpoint", Robert T. Frank, M.D., New York
4. "On the Relation of the Increta of the Adenohypophysis to the Disturbances of Growth and Development met with Clinically" Lewellys F. Barker, M.D., Baltimore, Md. (Invited Guest)

Wednesday, May 16th, at 2:00 P. M.

SYMPOSIUM: Forensic Medicine.

1. "Qualified Medico-Legal Experts; their value to the Community and to the Medical and Legal Profession", Charles Norris, M.D., New York
2. "Causes of Sudden Death", Harrison S. Martland, M.D., Newark, N. J. (Invited Guest)
3. "The Personality Makeup of the Criminal", Vernon C. Branham, M.D., Albany
4. "The Role of Toxicology in a Medico-Legal Autopsy", Alexander O. Gettler, Ph.D., New York (Invited Guest)

THE SECTIONS

All papers read before the Society by members become the property of the Society. The original copy of each paper shall be left with the Secretary of the Section. Discussors should have their remarks typed and hand them to the Secretary if they wish them published. Section meetings shall begin promptly at the hour specified.

SECTION ON MEDICINE

CHAIRMAN.....ALFRED M. WEDD, M.D., CLIFTON SPRINGS
SECRETARY.....FRANK BETHEL CROSS, M.D., BROOKLYN

Place of Meeting—Westminster Church House, First Floor

Tuesday, May 15th, at 10:00 A. M.

1. "The Irritable Colon", H. Walden Retan, M.D., Syracuse
Discussion opened by A. H. Aaron, M.D., Buffalo.

2. "The Early Recognition of Peripheral Venous Thrombosis", Meyer A. Rabinowitz, M.D., Brooklyn

Discussion opened by Adrian S. Taylor, M.D., Clifton Springs

3. "Interrelations of Neuropsychiatry and General Medicine", Foster Kennedy, M.D., New York

Discussion opened by Nelson G. Russell, M.D., Buffalo

Wednesday, May 16th, at 9:00 A. M.

1. "Practical Diagnosis and Treatment of Anemia", Stuart L. Vaughan, M.D., Buffalo

Discussion opened by John S. Lawrence, M.D., Rochester

2. "Tissue Reactivity to Streptococci and its Bearing on the Problem of Arthritis", Charles H. Hitchcock, M.D., Syracuse

Discussion opened by William B. Rawls, M.D., New York

3. "The Clinical Importance of Plasma Proteins", William S. McCann, M.D., Rochester

Discussion opened by David A. Haller, M.D., Rochester

4. "Observations on Conditions that May Simulate 'Angina Pectoris'", Emanuel Libman, M.D., New York

Discussion opened by Alexander Lambert, M.D., New York

SECTION ON SURGERY

CHAIRMAN.....FLOYD S. WINSLOW, M.D., ROCHESTER
SECRETARYEDGAR A. VANDER VEER, M.D., ALBANY

Place of Meeting—Hotel Martin, Ballroom.

Tuesday, May 15th, at 10:00 A. M.

1. "Bone Tumors and Allied Conditions", James Morley Hitzrot, M. D., New York

Discussion opened by Philip L. Forster, Albany

2. "Treatment of Angina Pectoris and Congestive Heart Failure by Complete Ablation of the Thyroid Gland"

Medical Aspects, Herrmann L. Blumgart, M.D., Boston, (Mass. (Invited Guest)
Surgical Aspects, David D. Berlin, M.D., Boston, Mass. (Invited Guest)

Discussion opened by W. Barkley Parsons, M.D., New York

Wednesday, May 16th, at 9:00 A. M.

SYMPOSIUM: Peptic Ulcer

1. "History of the Surgery of Peptic Ulcer", William D. Johnson, M.D., Batavia
2. "A Study of 671 Peptic Ulcers with Special Emphasis on 114 Postoperative Cases", Reynold E. Church, M.D., New York, and J. William Hinton, M.D., New York

3. "Some Pitfalls in the Treatment of Gastric Ulcer", W. J. Merle Scott, M.D., Rochester
 4. "Choice of Operation in Peptic Ulcer", George J. Heuer, M.D., New York
Discussion opened by Hyzer W. Jones, M.D., Utica
-

SECTION ON OBSTETRICS AND GYNECOLOGY

CHAIRMAN.....MILTON G. POTTER, M.D., BUFFALO

SECRETARY.....HOWARD C. TAYLOR, JR., M.D., NEW YORK

Place of Meeting—Westminster Church House, First Floor

Tuesday, May 15th, at 10:00 A. M.

1. "Basal Metabolism during Pregnancy", Edward C. Hughes, M.D., Syracuse
Discussion opened by J. Thornton Wallace, M.D., Jackson Heights
 2. "Minor Complaints of Pregnancy", Charles J. Marshall, M.D., Binghamton
Discussion opened by George H. Bonnefond, M.D., Utica
 3. "Technique of Obstetrical Forceps", Motion Picture Demonstration, William T. Getman, M.D., Buffalo
Discussion opened by James K. Quigley, M.D., Rochester
-

Wednesday, May 16th, at 9:00 A. M.

1. "Experimental Evaluation of the Use of Some Vaginal Antiseptics during Labor", R. Gordon Douglas, M.D., New York, and Henrietta S. Rhees, M.S., New York (Invited Guest)
Discussion opened by Henricus J. Stander, M.D., New York
 2. "Early Diagnosis of Cervical Carcinoma", Nathan P. Sears, M.D., Syracuse
Discussion opened by Howard C. Taylor, Jr., M.D., New York
 3. "Conservation of the Fundus Uteri", Herbert F. Traut, M.D., New York
Discussion opened by Henricus J. Stander, M.D., New York
 4. "Study and Treatment of Amenorrhea", C. Arthur Elden, M.D., Rochester
Discussion opened by Karl M. Wilson, M.D., Rochester
-

SECTION ON NEUROLOGY AND PSYCHIATRY

CHAIRMAN.....LEON H. CORNWALL, M.D., NEW YORK

SECRETARY.....JOHN L. ECKEL, M.D., BUFFALO

Place of Meeting—Westminster Church House, Second Floor

Tuesday, May 15th, at 10:00 A. M.

1. "Neuropsychiatric Considerations of the Sequelae of Head Injuries", Nathan Savitsky, M.D., New York
Discussion opened by Eugene N. Boudreau, M.D., Syracuse

- 2 "The Modern Psychiatric Hospital in Relation to Public Health", William W Wright, M D, Marey
Discussion opened by Richard H Hutchings, M D, Utica
 - 3 "Neurological Aspects and Treatment of Birth Injuries, with Motion Picture Demonstration", Earl R Carlson, M D, New York, and Walter O Klingman, M D, New York
Discussion opened by Rosalind G Freeman Jr M D, New York
 - 4 "Practical Diagnostic and Therapeutic Considerations in Anterior Poliomyelitis", Irving J Sands, M D, Brooklyn
Discussion opened by Paul H Garvey, M D, Rochester, and A Clement Silverman, M D, Syracuse
 - 5 "Recent Advances in the Treatment of Epidemic Encephalitis", Josephine B Neal, M D, New York
Discussion opened by Edward B Angell, M D, Rochester
-

Wednesday, May 16th, at 9 00 A M

- 1 "The Circle of Willis, Its Anomalies and Aneurysms", with Lantern Slide Demonstration, Wardner D Ayer, M D, Syracuse
Discussion opened by Edwin G Zabriskie, M D, New York
 - 2 "Psychological Factors in Respiratory Syndrome" Clarence P Oberndorf, M D, New York
Discussion opened by Harry A Steckel, M D, Syracuse
 - 3 "Intermittent Obstruction of the Foramen of Monro by Tumors of the Third Ventricle", with Lantern Slide Demonstration, Byron Stookey, M D, New York
Discussion opened by William P Van Wageningen, M D, Rochester
 - 4 "A Neuroendocrine Concept of the Cerebral Gland", with Lantern Slide Demonstration, Irving H Pardee, M D, New York
Discussion opened by James W Putnam, M D, Buffalo
 - 5 "Vegetative Disorders of Cerebral Origin", with Lantern Slide Demonstration, Joseph H Globus, M D, New York
Discussion opened by Nelson K Fromm M D, Albany
-

SECTION ON PEDIATRICS

CHAIRMAN	ADOLPH G DE SANCTIS M D NEW YORK
VICE CHAIRMAN	GEORGE C SINCERBEAUX M D AUBURN
SECRETARY	GEORGE M RETAN, M D SYRACUSE

Place of Meeting—Westminster Church House, Third Floor

Tuesday, May 15th, at 10 00 A M

- 1 "A Study in Infant Stools", with Lantern Slide Demonstration, Frank van der Bogert, M D, Schenectady
Discussion opened by Arthur W Benson, M D, Troy
- 2 "The Value of Continuous Intravenous Method of Fluid Administration (Venoclysis) in Pediatrics", Samuel Karelitz, M D, New York
Discussion opened by John Dorsey Craig, M D, New York
- 3 "Epilepsy of Allergic Origin", T Wood Clarke, M D, Utica
Discussion opened by Brewster C Doust, M D, Syracuse

4. "Cutaneous Reactions to Hemolytic Streptococcus Nucleoprotein in Rheumatic and Nonrheumatic Children", Albert D. Kaiser, M.D., Rochester
Discussion opened by Samuel W. Clausen, M.D., Rochester

Wednesday, May 16th, at 9:00 A. M.

1. "Clinical Aspects of Forced Perivascular Drainage of the Central Nervous System", with Motion Picture Demonstration, George M. Retan, M.D., Syracuse
Discussion opened by Orren D. Chapman, M.D., Syracuse (Invited Guest)
2. "Treatment of Erythroblastosis of the New Born", Douglas P. Arnold, M.D., Buffalo
Discussion opened by A. Wilmot Jacobsen, M.D., Buffalo
3. "A Clinical Survey of the More Common Diseases of the New Born", Roger H. Dennett, M.D., New York, and Leslie O. Ashton, M.D., New York
4. "The Problem of the Premature Infant", Ralph M. Tyson, M.D., Philadelphia, Pa. (Invited Guest)
Discussion of these two papers opened by Edward J. Wynkoop, M.D., Syracuse

SECTION ON DERMATOLOGY AND SYPHILOGY

CHAIRMAN.....GEORGE M. FISHER, M.D., UTICA
 SECRETARY.....FRANK C. COMBES, M.D., NEW YORK

Place of Meeting—Westminster Church House, First Floor

Tuesday, May 15th, at 10:00 A. M.

1. "Observations on Arsphenamine Dermatitis with Special Reference to the Reliability of the Patch Test", James W. Jordan, M.D., Buffalo
Discussion opened by Lopo de Mello, M.D., Syracuse
2. "The Clinical Interpretation of the Kline and Wassermann Tests", Leo Spiegel, M.D., New York, and Charles R. Rein, M.D., New York
Discussion opened by A. Benson Cannon, M.D., New York
3. "Sulpharsphenamine, Its Use and Status in New York State", Albert Pfeiffer, M.D., Albany
Discussion opened by Earl D. Osborne, M.D., Buffalo, and Harry D. Parkhurst, M.D., Utica

Discussion opened by Mark Heiman, M.D., Syracuse
5. "Studies on the Clinical Manifestations of Herpes", Albert R. McFarland, M.D., Rochester
Discussion opened by Jerome Kingsbury, M.D., New York
6. "The Leukocytes in Skin Diseases", Ray H. Rulinson, M.D., New York
Discussion opened by Howard Fox, M.D., New York
7. "Jonathan Hutchinson", Joseph V. Klauder, M.D., Philadelphia, Pa. (Invited Guest)

Wednesday, May 16th, at 9:00 A. M.

1. "Focal Infections as Related to Pustular Eruptions of the Hands and Feet", George C. Andrews, M.D., New York

- 2 "Pustular Psoriasis", David Bloom, M.D., New York

Discussion on these two papers opened by George M MacKee, M D, New York

3. "Studies in Eczema of Infancy and Childhood", Samuel M Peck, M.D., New York

Discussion opened by Abraham Walzer, M.D., Brooklyn

4. "Acne Vulgaris and Its Relationship to Other Acneform Eruptions", Marion B. Sulzberger, M.D., New York

Discussion opened by Herman Sharlit, M D, New York

SECTION ON OPHTHALMOLOGY AND OTOLARYNGOLOGY

CHAIRMAN..... .. FRANK M SULZMAN, M D, TROY

SECRETARY WEBB W. WELLS, M D, NEW YORK

Place of Meeting—Westminster Church House, Second Floor

Tuesday, May 15th, at 9:00 A. M.

Instructional Hour 9 00 A M to 10 00 A M

- a "Anesthesia, Local and General, Eye", Walter S Atkinson,
M D, Watertown

- b "Anesthesia, Local and General, Nose and Throat", Clayton
M. Brown, M D, Buffalo

- 1 "The Prevention of Hard of Hearing", Frederick J. O'Connor, M D,
Syracuse

*Discussion opened by John D. Carroll, M D, Troy, and Frederick A Lewis,
M D, Auburn*

2. "Treatment of Sinus Thrombosis", Truman L. Saunders, M D, New York
York

*Discussion opened by John F. Fairbairn, M D, Buffalo, and Samuel J Kopetzky,
M D, New York*

3. "Observations on Some Disturbances of the Vestibular Function", Page
Northington, M.D., New York

Discussion opened by Richard M. Brickner, M.D, New York

Wednesday, May 16th, at 8:30 A. M.

Instructional Hour 8 30 A. M. to 10 00 A. M

'Case Demonstration as to the Diagnosis and Treatment of Muscle
Anomalies", James W. White, M D, New York, and John H
Dunnington, M D, New York

1. "Cataract Extraction", Ben Witt Key, M D, New York

*Discussion opened by Albert C. Snell, M D, Rochester, Ernest F. Krug, M D,
New York, and Jason L. Wiley, M.D., Auburn*

2. "When Should a Senile Cataract Be Removed?", a Slitlamp Study and
Photographic Demonstration, Arthur J. Bedell, M.D., Albany

3. "Pathology of Immature and Mature Senile Cataract and of Adjacent
Zonular Fibers", Daniel B. Kirby, M.D., New York

*Discussion opened by John F Gagner, M D., Rochester, and David F. Gillette,
M.D, Syracuse*

SECTION ON PUBLIC HEALTH, HYGIENE AND SANITATION

CHAIRMAN.....STANLEY W. SAYER, M.D., GOUVERNEUR

SECRETARY.....WALTER A. LEONARD, M.D., CAMBRIDGE

Place of Meeting—Hotel Utica

Tuesday, May 15th, at 10:00 A. M.

Hotel Utica, English Room

1. "Clinical Experience with Vitamin D. Milk", Jacques M. Lewis, M.D., New York

Discussion opened by Paul B. Brooks, M.D., Albany

2. "Prevention and Treatment of Serum Sickness", James R. Wilson, M.D., Syracuse

Discussion opened by O. W. H. Mitchell, M.D., Syracuse

3. "Laboratory Developments in Diphtheria Immunization with Special Reference to One Dose Toxoid", William H. Park, M.D., New York

Discussion opened by Chalmer J. Longstreet, M.D., Binghamton, and Myron M. Metz, M.D., Williamsville

Wednesday, May 16th, at 9:00 A. M.

Hotel Utica, Ballroom

SYMPOSIUM: Asphyxia

1. "The Prevention of Asphyxiation During Anesthesia", Paluel J. Flagg, M.D., New York

2. "The Treatment of Asphyxia in Clinical Disease with Especial Reference to Recent Developments of the Use of Oxygen in Heart Failure", Alvan L. Barach, M.D., New York

3. "The Death Zone in Asphyxia", with Lantern Slide and Motion Picture Demonstration, Chevalier Jackson, M.D., Philadelphia, Pa. (Invited Guest), and Chevalier L. Jackson, M.D., Philadelphia, Pa. (Invited Guest)

SECTION ON UROLOGY

CHAIRMAN.....TERRY M. TOWNSEND, M.D., NEW YORK

SECRETARY.....THOMAS F. LAURIE, M.D., SYRACUSE

Place of Meeting—Westminster Church House, Third Floor

Tuesday, May 15th, at 10:00 A. M.

SYMPOSIUM: The Treatment of Gonorrhea

1. "Acute", Albert M. Crance, M.D., Geneva

2. "Chronic", Ernest M. Watson, M.D., Buffalo

3. "Gonorrhea in the Female", Robert N. Ritchie, M.D., Rochester

Discussion opened by Abraham L. Wolbarst, M.D., New York, and John E. Heslin, M.D., Albany

Wednesday, May 16th, at 9:00 A. M.

SYMPOSIUM: Obstructive Uropathy:

1. "Renal", Francis N. Kimball, M.D., New York

2. "Vesical", James N. Vander Veer, M.D., Albany

3. "Urethral", Arthur H. Paine, M.D., Rochester

Discussion opened by Oswald S. Lowsley, M.D., New York, and J. Sturdivant Read, M.D., Brooklyn

SECTION ON RADIOLOGY

CHAIRMAN JOSEPH M. STEINER, M.D., New York
 VICE CHAIRMAN DONALD S. CHILDS, M.D., Syracuse
 SECRETARY LEO P. LARKIN, M.D., Ithaca

Place of Meeting—Westminster Church House, Third Floor

Tuesday, May 15th, at 10 00 A. M.

- 1 "Cancer of the Tonsil", James J. Duffy, M.D., New York
 - 2 "Palliative Irradiation of Inoperable Gastric Cancer", George T. Pack, M.D., New York
 - 3 "Cancer Research", Francis Carter Wood, M.D., New York
 - 4 "Postoperative Roentgen Therapy for Carcinoma of the Breast", Maurice Lenz, M.D., New York, Haig H. Kasabach, M.D., New York
- General Discussion opened by Douglas Quick, M.D., New York, and Virginia K. Frantz, New York*

Wednesday, May 16th, at 9 00 A. M.

- 1 "Encephalography", Cornelius G. Dyke, M.D., New York
Discussion opened by Charles W. Schwartz, M.D., New York
- 2 "Bronchography", Leopold Jachies, M.D., New York and Isidor F. Shapiro, M.D., New York
Discussion opened by James M. Flynn, M.D., Rochester
- 3 "Small Intestine, the Major and Minor Motor Phenomena and Their Differentiation from Pathological Lesions", Lewis Gregory Cole, M.D., New York
Discussion opened by Donald S. Childs, M.D., Syracuse
- 4 "Low and High Power Roentgenographic Studies of the Sigmoid", William H. Stewart, M.D., New York, and Henry E. Illick, M.D., New York
Discussion opened by Ulysses S. Kann, M.D., Binghamton
- 5 "Excretion Urography and Its Value to the Radiologist", Leo P. Larkin, M.D., Ithaca
Discussion opened by Lester Lezyn, M.D., Buffalo

SESSION ON PHYSICAL THERAPY

CHAIRMAN RICHARD KOVACS, M.D., New York

Place of Meeting—Hotel Utica, English Room

Wednesday, May 16th, at 9 00 A. M.

- 1 "The Physical Therapy Department in a Hospital", Frederick E. Bauer, M.D., New York
Discussion opened by Lee A. Hadley, M.D., Syracuse, and Kristian G. Hansson, M.D., New York
- 2 "Physical Therapy in General Practice", Harold J. Harris, M.D., Westport
Discussion opened by Madge C. L. McGunness, M.D., New York, and Guy H. Turiell, M.D., Smithtown Branch
- 3 "Physical Therapy in Industrial Injuries", John B. Stevens, M.D., Syracuse
Discussion opened by Homer J. Knickerbocker, M.D., Geneva, and James W. Wulstie, M.D., Binghamton
- 4 "The Work of the Council on Physical Therapy of the American Medical Association", John S. Coulter, M.D., Chicago, Ill. (Invited Guest)
Discussion opened by Thomas P. Farmer, M.D., Syracuse, and Richard Kovacs, M.D., New York
- 5 "Physical Therapy in a Health Resort", Walter S. McClellan, M.D., Saratoga Springs
Discussion opened by George S. Towne, M.D., Saratoga Springs, and John DeP. Currence, M.D., New York

Scientific Exhibit

Hotel Martin, Rotunda, Mezzanine, and Connecting Corridor

NEW YORK STATE DEPARTMENT OF HEALTH LABORATORY DIVISION

Title: Laboratory Aids in Diagnosis

Description: Data will be exhibited relative to Amoebiasis, Bacillary Dysentery, Infectious Moniliasis, Granular and Floccular Agglutination of *Bacillus Typhosus*, foci of infection in Undulant Fever.

RUTH GILBERT, M.D.

DRS. W. H. CARY and R. S. HOTCHKISS
New York

Title: Evaluation of Male Fertility

Description: Microcinema of different behavior types of human spermatozoa. The fertilization of the sea urchin egg is depicted demonstrating the final interaction between egg and sperm.

ROBERT S. HOTCHKISS, M.D.

PHYSICAL THERAPY COUNCIL OF THE AMERICAN MEDICAL ASSOCIATION

Title: The Therapeutic Effects of Heat, Hydrotherapy and Exercise

Description: Exhibit consists of motion pictures and charts designed to substantiate the physiological effects of physical therapy procedures.

THOMAS G. HULL, M.D.

DR. ABE L. WOLBARST
New York

Title: Pathology of the Verumontanum and Posterior Urethra in Chronic Gonorrhea

Description: Exhibit consists of 16 wax models illustrating pathologic conditions in the posterior urethra as seen by aid of cystourethroscope. Also chart illustrating technique of Five Glass Catheter Test in Chronic Gonorrhea.

ABE L. WOLBARST, M.D.

COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY DEPARTMENT OF OPHTHALMOLOGY

Title: Color Photographs of Anterior Segment

Description: Stereoscopic transparencies of diseases of the external eye showing pathology of lids, conjunctivae, cornea, anterior chamber, iris and lens.

DAVID F. GILLETTE, M.D.

COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY
DRS. JANE SANDS ROBB and J. G. FRED HISS

Title: Ventricular Muscles and their Coronary Blood Supply

Description: Dissections and injections of hearts, demonstrating the component muscles and their blood supply. Also charts showing characteristic electrocardiograms when individual muscles are eliminated.

JANE SANDS ROBB, M.D.

COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY
DEPARTMENTS OF CLINICAL PATHOLOGY AND PHOTOGRAPHY

Title: Blood Diseases

Description: Natural Color Photomicrographs x 1200, taken from stained blood smears showing common and rare blood conditions. Transparencies. Viewing Frames. Lantern Projections.

WILLIAM A. GROAT, M.D.
STELLA ZIMMER, R.N.

DR. THOMPSON STEVENS
New York

Title: Irradiation in Thyrotoxicosis

Description: Statistical charts of the results of treatment. Photographs of technique employed in treatment by roentgen ray and radium. Photographs and histories of patients.

THOMPSON STEVENS, M.D.

MEDICAL SCHOOL, UNIVERSITY OF BUFFALO

Title: The Renal Tubule—Normal and Injured

Description: Structural and functional differentiation of the renal unit in the kidney of vertebrates with actual and photographic demonstration.

J. GRAHAM EDWARDS, M.D.

STATE INSTITUTE FOR STUDY OF MALIGNANT DISEASES
DR. BURTON T. SIMPSON

Title: Malignant Neoplasms

Description: A study of malignant neoplasms from different organs of the body portrayed by means of transparencies with history, description of the lesion, pathological diagnosis, treatment and results.

LOUIS C. KRESS, M.D.

DR. KEITH KAHN
New York

Title: Plastic Surgery (nose)

Description: Photographs, before and after operation. A series of plaster casts will be exhibited.

KEITH KAHN, M.D.

NEW YORK LEAGUE FOR THE HARD OF HEARING, INC.
New York

Title: Better Hearing for the State's Children

Description: Exhibit consists of charts, photographs and audiometers.

ESTELLE SAMUELSON.

DR. ARTHUR J. BEDELL
Albany

Title: Colored Photographs of the Eye

Description: A large collection of colored stereoscopic photographs of diseases of the external eye also stereoscopic pictures illustrating the various types of cataract presented in conjunction with a paper before the Section on Ophthalmology on, "When Should a Senile Cataract be Removed?"

DR. WILLIAM S. COLLENS
Brooklyn

Title: "Simple Methods for Writing Scientific Diets," and "One Hundred Obesity Diets on One Chart"

Description: Exhibit consists of illustrative charts.

WILLIAM S. COLLENS, M.D.

DR. WILLIAM F. JACOBS
Buffalo

Title: Educational Anatomical Material from Laboratory of Pathology, University of Buffalo, and Buffalo City Hospital

Description: Educational cinema on Trichinosis. Corrosive specimens of the renal arterial tree mounted with companion kidney in arterionephrosclerosis. Large histological sections of lungs in pulmonary lesions.

WILLIAM F. JACOBS, M.D.

DR. ERNEST B. HANAN
Buffalo

Title: Hematological Studies Graphically Represented

Description: Hematological graphs from a series of case studies.

ERNEST B. HANAN, M.D.

ALEXANDER O. GETTLER, PH.D.
New York

Title: Medical Legal Toxicology

Description: Illustrative examples of Toxicology with demonstrations. Case records and material illustrative of causes of sudden death.

ALEXANDER O. GETTLER, Ph.D.

SOCIETY FOR THE PREVENTION OF ASPHYXIAL DEATH, INC.
New York

Title: Asphyxial Death

Description: Gross and microscopic specimens illustrating the principal causes of acute asphyxiation.

PALUEL J. FLAGG, M.D.

Commercial Exhibit

Hotel Martin, Mezzazine Floor

Beech-Nut Packing Co Beech-Nut Strained Foods are made from selected raw materials high in mineral and vitamin value. These have been protected and conserved to a high degree in the preparation of Beech-Nut strained cereals, fruits, and vegetables by cooking them in a high vacuum, using the least possible water and preserving all juices so that nothing is lost. This scientific process insures greater uniformity and digestibility, both important to the baby and to invalids or convalescents as well.

No preservatives, whether permitted by law or not (and this includes sulphur dioxide), nor any coloring matter of any kind, whether legally approved or not, are used in these foods in any form. Call at booth 18 for samples.

Bilhuber-Knoll Corp. For the successful treatment of heart disease, Theocalcin (theobromine calcium salicylate), a well tolerated myocardial stimulant and diuretic, is widely used. Theocalcin and the other fine medicinal chemicals of this well-known firm will be found at Booth No. 20.

Dermatologists will be interested in Euresol for scorreic conditions of the skin and scalp and Lemgallol, for chronic eczemas.

The cardio respiratory restorative Metrazol, will also be featured. Metrazol is of interest for emergencies as shock, infantile asphyxia and in pneumonia.

Davies, Rose & Co, Ltd (Booth 21) Those who do not know of this firm's Standardized Pills of Stramonium Leaves, employed in the treatment of postencephalic symptoms, will doubtless wish to make a point of investigating this product. Mr R J Mansfield and Mr H V Orne will be in attendance to give full information on it. They will also be glad to discuss Pil Digitalis (Davies, Rose) with physicians who may not already be familiar with this dependable form of administering digitalis.

Sandoz Chemical Works, Inc, will feature 'Calglucon,' pioneer calcium product whose introduction has considerably widened the field of applicability of calcium therapy. It is well tolerated orally, safe and non-irritant for intravenous and intramuscular injection. A special process insures perfect stability of the ampule solution and guarantees the utmost in tolerance and therapeutic effectiveness—'Gyneugen' is the original and only product containing the specific ergot alkaloid 'ergotamine' in pure and stable form. It is the only ergot product in New and Nonofficial Remedies recommended for both oral and subcutaneous use.—In the field of heart therapy, 'Scillaren' and 'Scillaren'-B, new glucosidal principles of squill will be featured.—Competent representatives will be in attendance at Booth No. 3 to answer questions pertaining to these products as well as other Sandoz preparations.

Merck & Co, Inc In Booth No. 6 will be displayed such well known preparations as NEOARSPHENAMINE for the treatment of syphilis, TRYPARSAMIDE for the treatment of Paresis, STOVARSOL for a mebic dysentery, DIGITAN for heart diseases, ERYTHROL TETRANITRATE for hypertension, BISMOSOL, a water soluble preparation for intramuscular use in syphilis. A few of Merck's prescription chemicals will also be shown. The Merck booth is always an attractive center of interest and will be in charge of Mr Kraus and Mr Reilly, who will give you full data on the above preparations.

Sanborn Co The 1934 Sanborn Motor-Graf Metabolism Tester introducing the electrically driven Kymograf clock is on display in Booth 19. Other features are the quiet running motor-blower for circulation of air and oxygen, oxygen shut-off valve, mobile table finish in harmonizing colors with table to match main apparatus. The 1934 Sanborn Electric-Portocardiograf operates directly from lamp socket or wall plug, is complete in two compact attractive solid mahogany inlaid carrying cases with table to

match. This makes a sturdy and substantial office outfit as well as a conveniently portable outfit for testing at patient's homes.

E. R. Squibb & Sons. Members of the Medical Society of the State of New York are cordially invited to visit the Squibb booth, at which there will be displayed some of the new developments from the Squibb Laboratories.—Among the newer products featured will be Halibut-Liver Oil Concentrate Tablets, a new anti-anemic liver preparation, a new glandular product, a new product for Diphtheria immunization and a new calcium preparation with Vitamin D.

The Mutual Pharmacal Company, Inc., Syracuse, N. Y., will exhibit products of its laboratory during the April Meeting of the State Society in Utica, N. Y.

A cordial invitation is extended to physicians to visit booth 14, Technical Exhibit, Mezzanine floor, Hotel Martin.

R. B. Davis Company. Cocomalt—the scientific food concentrate that supplies a rich calcium, phosphorus and Vitamin D content in a particularly delicious form—is again being exhibited. Visit Booth No. 9 and enjoy some delicious Cocomalt served either hot or cold. Physicians report an ever-increasing use of Cocomalt in the diet. Interesting scientific data available.

The Foregger Co., Inc. To see the latest developments in anesthesia apparatus, and to find out how the annual cost of anesthetic gas and ether may be cut to an absolute minimum, while at the same time increasing the efficiency of the anesthesia staff, pay a visit to the exhibit of the Foregger Company, Booth No. 1 and ask about the Filter method of anesthesia. A complete line of airways, endotracheal catheters and adapters and laryngoscopes will be shown.

There will also be a number of resuscitation units to be seen, besides oxygen therapy apparatus of simple and efficient design, inexpensive enough for the present day budget.

Gerber Products Co. Visitors at Booth No. 5 will be shown the Gerber's Strained Cereal, Vegetables, and Prunes and given any information desired concerning the special process used in the manufacture of these products.

Booklets are available. One on infant feeding is intended for distribution by physicians to mothers and contains help on the technique of feeding without giving definite feeding directions. There are several publications on the use of these products in therapeutic diets, some for professional use only and others for general distribution.

H. J. Heinz Co. Heinz Strained Foods for baby feeding, special soft diets, and convalescents are featured. The varieties are Spinach, Carrots, Peas, Green Beans, Tomatoes, Beets, Prunes and Vegetable Soup. Only fresh vegetables of select quality are used in preparing these products. A special vacuum process conserves in high degree the natural vitamins and mineral salts.

Other Heinz varieties being exhibited are Olive Oil, Rice Flakes and Breakfast Wheat. An outstanding feature of the Heinz cereals is their content of added Cereal Cellulose which has a gentle laxative action through furnishing bulk without irritation.

The Kalak Water Co. of New York, Inc., will occupy Booth No. 23 and invites physicians to visit the booth and learn how delicious and refreshing when properly served.

Obviously, the greatest use for Kalak Water is for routine use in the home when an alkaline water is indicated. It is generally recognized by physicians that the majority of people, and particularly those of sedentary habits, do not drink sufficient water, both for its value as a food and as an eliminant. Kalak solves this problem, for it combines purity and palatability.

Saratoga Springs Authority, Saratoga Springs, N.Y., Booth No. 10, will exhibit photographs and charts showing the treatments that are given at the State Sanatorium in addition to the display of bottled water.

The DeVilbiss Company, Toledo, Ohio, manufacturers of medicinal atomizers, will exhibit in Booth No. 13. The outstanding feature of this exhibit will be the new *vented nasal guard* which eliminates any possibility of excess pressure in the nasal cavities during prescribed self-treatment. In addition, a complete line of DeVilbiss Atomizers and Vaporizers (Nebulizers), for both home and professional use, will be displayed.

Mead Johnson & Company will have on exhibit its complete line of infant diet materials including Mead's Dextri-Maltose, Mead's Newfoundland Cod Liver Oil, Mead's Viosterol in Oil-250 D, Mead's 10 D Cod Liver Oil, Mead's (A-D) Viosterol in Halibut Liver Oil-250 D, Mead's Halibut Liver Oil, Mead's Brewers Yeast Powder, Mead's Brewers Yeast Tablets, Pabulum, Mead's Cereal, Sobee, Mead's Powdered Protein Milk, Mead's Powdered Lactic Acid Milk, Powdered Whole Milk, Alacta, Recolac and Casec. There will also be for the examination of physicians a complete line of Mead's services such as diets for older children, height and weight charts, etc., all of which are free to members of the medical profession in any quantity desired.

Representatives will be on hand to meet their friends and to discuss the application of any of the Mead products to infant feeding problems.

C. M. Sorensen Company, Booth No. 12, will have on display for your personal inspection several very interesting new models and combinations of Suction and Pressure Outfits, with their allied accessories for tonsil irrigation, coagulation and desiccation, where these are indicated in the treatment of the Ear, Nose and Throat.

Most efficient, compact and complete equipment ever designed—now available. A model for every purse and purpose. Scientific advancement in equipment is offered to you for your advantage and assistance in the daily problems of your Profession.

Radium Emanation Corp. An interesting and timely radium exhibit is to be a feature of the Annual Meeting of the Medical Society of the State of New York at Utica on May 14, 15 and 16. Representatives of The Radium Emanation Corporation of New York City will occupy booth 8, where you will find on display a large and varied assortment of radium and radon applicators and appliances specially designed to meet the present-day demands of the physician who would employ radium therapy scientifically and accurately.

The Radium Emanation Corporation has been serving the medical profession in North America since 1923. If you want first-hand information as to how you can personally utilize the radium resources and technical facilities of this organization, a visit to booth 8 should prove both interesting and profitable.

Fruit Belt Preserving Company, of East Williamson, New York, New York State's Famous Fruit and Vegetables now available for special diets.

Pixie Strained Fruits and Vegetables, prepared by this Company, one of New York State's best known quality packers, are now available at pharmacies and food stores throughout the State. These products, prescribed where soft diets are indicated, come in nine varieties. Accepted by the Committee on Foods of the A.M.A.

Winthrop-Metz. At Booth No. 2 you will find an exhibit featuring such well known sedatives and hypnotics as Adalin, Phanodorn and Luminal; Pyramidon, the dependable analgesic; Salyrgan, potent diuretic for cardio-renal and hepatic dropsy; Novocain and Novocain Crystals for local and spinal anesthesia; and the Salvarsans. Attention is also called to the informative pamphlets, some of which are profusely illustrated, on these products as well as on a number of more recent introductions.

The Metropolitan Life Insurance Company in Booth 24 will present material on the communicable disease problem in New York State as indicated by figures from the State Department of Health, and the extent to which these diseases are getting the nursing service offered by this Company to its policyholders.

Miss Sara O'Meara, the Company's Nursing Supervisor for New York State, will be in charge of the booth and will be prepared to discuss this particular angle of the nursing service as well as to the service in general.

Child Labor Amendment Dangers

The Medical Society of the State of New York is opposed to the ratification of the proposed Child Labor Amendment to the Constitution of the United States.

The Society is opposed to child labor, and at the same time is opposed to the amendment that ostensibly aims to end child labor.

Why this seeming inconsistency? If we are against child labor, why not support the amendment authorizing Congress to put a stop to it? The reasons for this paradox are clear as daylight if we stop to think the matter through.

First of all, President Roosevelt said in his message to Congress on January 3rd, "Child labor is abolished." The amendment, therefore, is not needed. In the next place, "all the states now have proper legislation covering the ages generally recognized as subjects of protection," according to Clarence E. Martin, former president of the American Bar Association. But the most weighty reason of all, the one that has roused the opposition of men we all respect, is that the amendment would give Congress powers that might easily become tyrannical and dangerous.

The vicious character of the amendment was so plain ten years ago, in fact, when

it passed the Congress, that the legislatures of 26 States promptly voted against ratification, and in 12 other States one house of the legislature opposed it. It was supposedly defeated, but now its supporters are starting a fresh campaign in the hope that the legislatures of to-day will reverse the verdict.

The proposed amendment reads:

"Section 1. The Congress shall have the power to limit, regulate and prohibit the labor of persons under eighteen years of age.

"Section 2. The power of the several states is unimpaired by this article, except that the operation of state laws shall be suspended to the extent necessary to give effect to legislation enacted by the Congress."

The "joker" in it, as it is called by no less an authority than former President A. Lawrence Lowell of Harvard, lies in the first section, which gives Congress full "power to limit, regulate and prohibit the labor" of all under 18. These words sound very mild and innocent, very much like those in the original constitution giving Congress the power "to regulate commerce . . . among the several states." When the Constitution was written, there was so little commerce among the several states that few probably gave this clause a second thought. Now no railroad dares draw its breath, or at least draw up a schedule of freight rates, without the permission of Interstate Commerce Commission. Space forbids even an enumeration of the acts of Congress, under this simple clause, reaching into the furthest corners of the nation and affecting every industry that ships so much as a peanut or a tin whistle across a state line. Now this new amendment uses the same word, and would empower Congress to "regulate" the labor of all under 18.

There are about 45,000,000 persons in the United States under 18 years of age, we are told, who would be subject to inspection and regulation by any bureau set up by Congress under this amendment. The measure makes no distinction between work for wages and voluntary work in the home or on the farm. Archbishop Glennon, speaking at St. Louis in December,

said: "We have no right to concede, you parents have no right to concede, to the United States Government, the right to regulate the lives of our children." President Henry S. Pritchett, of the Carnegie Foundation for the Advancement of Teaching, remarks that many find usefulness, happiness and their best development in gainful occupations before they are 18, and, he adds: "To confide to a Federal bureau in Washington the power to decide this question for all such persons in the United States is bureaucracy gone mad." The case cannot be stated better than in the words of President Lowell. In a radio broadcast on February 16 he quoted the proposed amendment, and said:

"This certainly grants authority to prescribe what work all young people up to eighteen years of age shall not do, and what they must do. It would empower Congress to forbid them to do any work, whether paid or unpaid, on any farm, garden or in the household, by way of assisting their parents or otherwise; to prohibit a youth whose father was dead from helping his mother by milking the cows or doing the chores out of school hours; or a girl whose mother had died from taking care of the younger children.

"So much for what Congress could do under the power to limit and prohibit work; but it can also regulate and therefore prescribe. Suppose, for example, it should ordain military drill for all boys. Would not that be a kind of labor? It certainly is not play. Will anyone assert that the Supreme Court would hold such an act unconstitutional as beyond the power conferred by this amendment? Is the supposition absurd?

"Let us not be dogmatic, or too sure what enthusiasm or excitement may or may not produce, but ask ourselves why should we confer authority if we do not want it used. Where power is granted there is always a tendency to use it.

"Much of the crime committed by young men at the present day is due to the fact that they have not acquired the habit of work and respect for it during the period when habits and character are formed. Work should not, of course, interfere with schooling, but outside of school duties it

is good if properly conducted. For a well-grown boy to help his father on the farm, in the garden, or in the family chores, with a sense of responsibility for the work to be done, is invaluable in teaching the serious aspects of life; and in the same way for the girl to take part with her mother in household labor is a normal preparation for the making of her own future home.

"Do we desire, as in the case of Prohibition, any army of officials to administer this amendment? Do we want them—outside of mechanical industry—supervising our young people, prying into private life, sending questionnaires to parents, under penalty if not answered or answered wrongly? Of course, we do not want such things; but if not, why grant the power with a childlike confidence that it will not be used in a way we do not like? Have we not had our lesson and suffered from it?"

The position of the Medical Society of the State of New York is that this is a State matter which should be handled by the legislature in cooperation with the State Medical Society, a body amply competent to see that the health of the children is fully protected.

That Little "Drop of Ink"

It "makes millions think," if we are to believe the old adage, and there is no reason why the medical profession should not use it, within ethical limits, just as well as anyone else. An excellent example is afforded by the Medical Society of Westchester County, which has established cordial relations with the various newspapers throughout the county and furnishes medical information to them of the same nature as the New York Academy of Medicine gives to the press of New York City. Whenever a question arises as to the authenticity of any medical news, the editor can query the office of the society and get the right of it.

The newspapers of the county copy some item, article, or editorial from the society's Bulletin nearly every month. Sometimes an entire leading article is taken bodily and played up in a prominent position. In fact, a certain group of county

journals have declared it to be their policy to build up the County Medical Society in the public mind to the point where its attitude on any health subject will be taken as absolutely authoritative. Take, for example, the report of the Economic Committee of the County Society last November on the value of the free medical care given by physicians and surgeons in hospitals and dispensaries. The county papers give it the widest publicity. The resolution pointing out the dangers of too drastic cuts in county hospital appropriations was also broadcast all over the county by the press, and given hearty editorial endorsement.

The effect of all this on the public mind is excellent. What has been done in Westchester County can be done equally well in many other counties. With such publicity in the press, and with ethical health talks on the radio, such as some other County Societies are sponsoring, the influence of medical charlatans can be counteracted and the public can be brought into touch with proper medical advice and service.

A Record Written in Human Lives

This State may well be proud of its record in providing medical and nursing care for its unemployed in 1933, and at the same time feel gratified at the low cost at which the service was rendered. The well-nigh incredible fact is that the medical care provided for the jobless in their homes or in the doctors' offices took less than 2 per cent of the total home relief expenditure during the year. In short, the average expenditure for medical care per family came to only \$4.21, or about the cost of a new hat. It should be kept in mind, too, that these figures do not include the ordinary clinic and out-patient services. They represent actual visits to the patient's home or consultation in the doctor's office.

We have another surprise when we run our eye over the table of figures and separate the items for city and country. The cost runs high in the country, it appears, and low in the city. Thus, the cost of medical care of the workless in cities of 100,000 and over was only \$1.94 per

year per family, about the price of a roast of beef for the Sunday dinner. In cities ranging from 50,000 to 100,000 it was \$3.17; in cities between 25,000 and 50,000 it was \$6.85; in cities under 25,000 it was \$6.81, while in the counties it rose to \$11.59, or nearly a dollar a month. Think of medical care at that figure. What price health! Almost a dollar a month! Less than many a man pays for shoe-shines. We see here a superb background of devotion to service by the men who cared for the jobless at these pitiful figures—often, no doubt, not enough to pay the doctor's actual expenses.

The nurses, too, played a splendid part in this fine work. A "double relief" plan was developed by the TERA in cooperation with the district state health officers and nurses, under which an average of about 200 nurses needing relief gave nursing care to the unemployed in nearly 60 communities. They made the amazing total of 30,000 to 40,000 visits per month at an average monthly cost to the state of less than \$13,000.00, or about 35 or 40 cents a visit! But were the nurses satisfied with this service? Not at all. It merely gave them an appetite for more, so they launched out into the promotion of local public health activities such as immunization campaigns, nutrition surveys, and child welfare activities. The plan of "double relief" became very popular, according to the State Department of Health, a statement that certainly "sounds reasonable," and during the last two months of the year the nursing service was expanded to include 500 to 700 nurses working in about 100 of the 116 welfare districts in the State.

A notable feature of the program was evolved with the aid of the State and county medical societies, cooperating with the State TERA in the State Department of Health. It provided a more uniform and effective medical service to unemployed families at a moderate cost to the state and local relief funds. A set of "Rules and Regulations Governing Medical Care of Home Relief Clients" was drawn up at the request of the then chairman of the TERA, Mr. Harry L. Hopkins. It was "formulated by a committee

comprised of Thomas Parran, Jr., M.D., state commissioner of health, and James N. Vander Veer, M.D., A. G. Swift, M.D., and H. W. Jones, M.D., representing the State Medical Society and H. Jackson Davis, M.D., a staff member of the State Department of Health who has been acting as Director of Medical Care for the Temporary Emergency Relief Administration. These rules and regulations were officially adopted without material change by the Relief Administration on March 3, 1933." Later, Mr. Hopkins became Federal Emergency Relief Administrator, and these regulations, with the approval of representatives of the American Medical Association and the United States Public Health Service, were adopted by the Federal Emergency Relief Administration in October last.

This record of New York State in caring for the health of the unemployed may well stir the pride of the profession, and if your good deeds are or are not written in shining volumes off somewhere beyond the stars, they are written in the happier and healthier lives of men, women and children here and now.

The More Prosperity, the More Accidents

As the wheels of industry start to speed up, they begin again to exact their toll of life and limb which has been mercifully lowered during the depression. Statistics show that last year there were only 14,000 occupational deaths in the United States as compared with 20,000 in 1929. In other words, 6,000 people are alive today who would have been killed if prosperity and its accidents had continued. The nonfatal accidents, too, of course, rise and fall as the wheels spin faster or slower. They amount to a hundred times the number of fatal mishaps.

The statistical experts have reduced this to a science. It seems that for every ten thousand persons reemployed, anywhere from one to fifty or more will probably be killed within a year, according to the hazard of their occupation. So we are told by the Statistical Bulletin of the Metropolitan Life Insurance Company.

The curve of accidental injuries follows very closely the curve of employment it seems, despite all the achievements of accident prevention by many factories and, indeed, by entire industries.

What we have to keep in mind just now, too, is that many of the newly employed are inexperienced and so are more likely to have accidents, and even the old workers have been idle so long that they have lost a little of the knack of their trades, and may easily lose a finger or a hand in a lax moment. A word of caution from the physician to Jim and Bill and Mary and Kate as they return light-heartedly to work may be the very thing that will save them from disaster.

Blest Be the Ties That Bind

The imagination is tempted to run riot with the possibilities conjured up by the splendid gift announced at the dinner of the Pan American Medical Association. The anonymous donor is giving a sufficient sum to enable 42 young physicians from 21 Latin American countries, including Puerto Rico, to have a year of postgraduate training in United States hospitals. And more than that, it is hoped that funds will be provided to send 42 young United States physicians to spend a year as internes in South American hospitals. Each interne is to receive \$30 a month in addition to his traveling expenses and a year's subsistence. The announcement was made by Dr. Harlow Brooks, Vice-President of the Pan American Association, who allowed it to be known that the donor is a noted New York philanthropist who is interested in promoting a better understanding between the peoples of North and South America. The two representatives from each Latin American nation will be selected immediately by the organized medical profession of their country, and it is expected that they will all arrive here some time this spring and will be assigned to the large medical centers throughout the United States. It is hoped that such exchanges will be continued in future years.

Our rapidly growing trade with Latin America, the expanding tourist traffic, the fast, luxurious steamers, the airplane lines,

are all cementing the people of the northern and southern continents in closer and closer ties year by year. This warm hand-clasp of the medical professions, however, has something intimate about it that goes far deeper than the contacts of trade or the curiosity of the tourist. Men who have worked side by side in the hospital wards fighting the battles of life and death form friendships that endure. Here will be a tie that no other nations in the world enjoy. It is something new in international relations, founded in wisdom and based on the bedrock of common sense.

It must not be lightly supposed, either, that the advantages of this arrangement is all on one side. True, we can teach Latin America more or less in a medical way, no doubt, but we can learn, too, from these splendid young fellows who are to be our guests. Latin American culture has fine qualities about it that we can well assimilate. North America is the land of efficiency, of hurry, bustle and go-getting. But the Latin American has learned how to live—the North American hasn't found time for that yet. These young medicos are coming here to try to learn something from us that they can carry back to help their own people. Let us see if we cannot learn something equally valuable from them.

"Doctor" Shoes—What Next?

Quite a bit of comment in the medical journals and the organs of the boot and shoe trade has followed the discovery by a New York orthopedist that no less than 189 trade names for shoes carry the word "Doctor." They are "Dr. Blank's Shoes," or "Designed by Dr. So-and-So." Two questions rise at once—are the shoes really designed by doctors, and, if so, how can a doctor make any one shoe design for hundreds of different shapes of feet that he has never seen? "Since every foot differs from every other one," observes the *Jour. A.M.A.*, "it should be apparent that no shoe constructed according to a standardized type could be quite adequate for any deformed or weakened foot." Dr. Norman D. Mattison, of New York, has called the attention of the Federal Trade

Commission to this matter, and the Commission replies that it "is now being considered with a view to correction."

A moment's thought shows how ridiculous it is to suppose that an ordinary shoe salesman can take a pair of "Dr. Blank's Shoes" from a shelf and make them fit a buyer whose foot needs a special last. Journals of the shoe trade both here and abroad see how indefensible this advertising claim is. The "doctor" brands "are based upon 'bolony'," remarks the *Shoe and Leather Record*, of London, and it believes the trade here would do well to rid itself of a large number of them.

The tendency of such a practice is only to cheapen the value of the word "doctor." If we are to have 189 kinds of "doctor" shoes, how long before we shall have a thousand kinds of "doctor" hats, socks, handkerchiefs, pajamas and what-not? The profession is already plagued to distraction by the platoons of charlatans and mountebanks who pose as healers and miracle workers—why should the shoemakers, butchers, bakers and candlestick-makers join their ranks and pretend to be "doctors?"

A Crook Born Every Minute, Too

As fast as the crooks are put behind the bars a new crop seems to appear, as if the powers of darkness were feeding an endless supply of sharpers into our poor old world, afflicted enough already. It is a bit discouraging to realize, as we fight to cut down the infant death rate, that we are undoubtedly saving the lives, among the rest, of hundreds and perhaps thousands of future crooks. The baffling thing is that a baby crook can look and coo just as sweetly as a baby seraph, so nothing can be done about it at that stage, anyway.

What brings the painful subject up just now is the news that our old friends, the eyesight swindlers, are operating in Kentucky. Other states have experienced their delicate attentions many times in the past, but for some reason Kentucky has escaped their notice till now. They are there, however, with their "radium water," their "radium belts," etc. According to reports from Kentucky physicians, these rascals

first offer to treat the eyes of the afflicted person with the magical radium water, on an advance payment of several hundred dollars, with a guarantee that the money will be refunded unless the patient is definitely cured in a stated time.

Before the time is up, however, another member of the gang appears with the bad news that the radium water man has been killed in a motor accident, but that he has a marvelous radium belt that is just the thing for the patient's case. It is not for sale. No, no. Money would not buy it, for it is the only one of the kind in existence. The patient can rent it, however, for a small sum, if he will put up a large sum to guarantee its safe return. Of course, the swindler never comes back for the belt, and the money is lost.

If the supply of swindlers is endless, the supply of gullible—shall we say suckers—seems equally so. If the radium water and belt peddlers are driven from Kentucky, they are just as likely to turn up in this State as any other. At the first news of them the police should be put on their track.

Drug Pirates

Raids by the New York City police have uncovered a nefarious business that will rouse the concern of every physician. What the officers found was nothing less than a plant that has been distributing fake drugs, proprietary medicines and toilet preparations. Labels, boxes, bottles, cartons, all were imitated to the last point of perfection. But the products inside were spurious. Headache tablets were made of talcum powder. Colored and flavored water masqueraded as cough medicine. What purported to be famous brands of patented medicine were discovered to contain actually harmful ingredients. A large bottling works was discovered that had every appearance of a branch of a famous fountain-drink concern. The delivery trucks, the employees in natty uniforms, the cases, the bottles, were all exact duplicates of the genuine ones. But the entire outfit was a fake.

Druggists interviewed say that this rascally work has been going on for some

five years. Nothing escaped imitation. Tinted and perfumed flour is sold under the guise of a well-known brand of talcum powder. Reputable druggists who pay around \$1.15 an ounce for an ephedrine product are offered a substitute for \$1.35 a pint. Spurious aspirin tablets, marked and boxed like the genuine, are offered at a huge reduction. Recall the large percentage of prescriptions that contain aspirin, and the harm done by cheap and worthless substitutes is apparent.

Remember, too, that the druggist who handles these products may not know that they are fakes. The piratical distributors represent them to be genuine, and give reasons, very plausible in these times, why prices are so low. However, the word has gone around about this sort of bootlegging, and the druggist who has not heard about it must be a rarity. One high-grade dealer, whose store has been in the same family some seventy-five years, says that the spurious stuff is marketed through the "five-board" drug-stores, third-rate outfits fitted up and run "on a shoe-string." No doubt it would not be beyond these bandits to operate drug stores of their own.

Another druggist expressed his fear some two or three years ago that his trade would be ruined by competitors selling imitation products at prices below the wholesale figure, but the fact that he is still doing business at the old stand seems to show that a goodly section of the public appreciates character and quality, especially when it affects their health and perhaps their lives.

One great difficulty of the situation is that the criminal laws fail to apply adequately, and in many cases the only recourse of the manufacturer whose product is imitated is a civil suit. Then, too, the drug faker can skip nimbly from city to city, from state to state, until it is almost impossible to stop his chicanery. The physician can do much to protect his patients by recommending druggists of high character and conscience. Legislative committees can urge the adoption of laws to put these unconscionable enemies of society behind the bars.

Correspondence

Anonymous letters will not be noticed All communications must carry full name and address of the writer but these are omitted on request

To the Editor

Perhaps while Uncle Sam is feeding us all alphabet soup' with an entree of codes and a salad of new planning, it is timely to offer a somewhat radical idea for the reestablishment of the family physician. Within the profession there is an opinion, increasingly expressed, that the field of general practice is being neglected for that of specialism.

There is no need to review here the changes in medical practice which have led to the present extent of the public assuming the role of medical adviser. Since the beginning of history, there have been cults and pseudoscientists who have sought to be guides in all matters pertaining to health, but to-day more or less everyone seems to have advice to offer and practically everything that is advertised depends, for its sales appeal, on some benefit to health and well being. The public has never before been so health conscious. Mostly through our own efforts, a smattering of the medical sciences has been spread abroad and, based on this primitive knowledge, the responsibility of diagnosing and prescribing is assumed by all. Where a physician might hesitate almost any layman recommends this or that medicine or treatment thoughtlessly and sometimes disastrously. The senselessness of paying a fee for advice as to a cough mixture or a cathartic when the radio and "The Doctor's Advice" columns give it free is only too apparent. And as to food, clothing, climate, recreation—why consult a physician unless one is actually ill. Nevertheless, if everyone had a family physician upon whose interested advice he felt he could confidently rely, this state of affairs would change almost automatically.

There is much complaint about the assumption of the status of specialist by doctors who are not fully equipped by study and experience to do so. The specialist was formerly the product of long years of service in general practice, with the development of special skill in a particular field and, finally the concentration of his entire attention exclusively to one system or to one region of the body. It was an end reached by natural growth. To-day a specialty is often selected by the premedical student and his education is consequently narrowed as much as possible to that subject. It is reported that MacKenzie, when asked by an American doctor what course to follow to fit himself as a heart specialist, advised his inquisitor to return home and take up general practice for fifteen years.

Various medical journals are commenting rather severely on the fact that some recent graduates of the medical schools seem to know very little about the use of drugs or even how to write prescriptions for them. They know the theories of vaccines, serums, and organic products but of the action of drugs that have proved their value they know nothing. Dr. Thomas A. McGoldrick, of Brooklyn, remarks

As a rule, the layman seeks the specialist who treats the organ which to him seems to be at fault, but very often the etiologic factor lies elsewhere. The duties of the family physician have been usurped by salesmen, boards of health, and specialists.

With this sketchy description of the present unsatisfactory conditions prevailing in the practice of medicine, let us propose our remedy. We do not expect you to accept it without studying its probable effects, but we beg you to at least give it some consideration before tossing it aside as impracticable. It seems to us that this remedy would purge the profession of pseudospecialists, elevate the family physician to the place of honor and importance he richly deserves, discourage laymen and organizations from practicing medicine and make more orderly the at present haphazard methods in vogue pertaining to the care and preservation of life.

This remedy is to establish the specialist as an instrument to be used solely by the family physician, the specialist seeing no patients except those referred by a family physician.

JOHN JOSEPH NUTT

To the Editor

There has been sent to me a copy of your review appearing in the February 15th issue vol 34, page 174 of the NEW YORK STATE JOURNAL OF MEDICINE, of "The Diseases of Infants and Children" by J. P. Crozer Griffith and myself.

It would seem quite unbecoming for an author to make any particular comment on a review of his book, but I do feel that there is a misstatement in it which might be called to the attention of the reviewer. According to the copy sent me there is a statement that in the treatment of chorea there is no mention of the newer shock methods such as nirvanol and typhoid vaccine.

The treatment with nirvanol is mentioned at some length on page 878, and there is reference to Sutton's work on foreign protein therapy for the production of fever, with the reference given. I think that it is quite probable that more space might have been given to the treatment by foreign protein therapy, although I think also that the comments made on treatment of chorea in general on page 878 quite obviate the necessity for discussing the numerous treatments advocated.

A. GRAEME MITCHELL, M.D.

in the *Medical Times* that it shocks doctors who were graduated many years ago to learn that medical schools to day do not teach Materia Medica and Therapeutics as they understand the terms. He is not surprised that so many young doctors write a prescription for the same ingredients which the druggist could put up at a fraction of the cost to the advantage of both patient and physician.

Society News

The School Health Program for the Hard of Hearing Child

2. The Rural and Urban Projects in Westchester County

ANNETTA W. PECK

Executive Secretary, The New York League for the Hard of Hearing, Inc.

It is proposed to show in this article, which is the second of the series sponsored by the committee on the deaf and the hard of hearing, how two projects, conditioned by contrasting environments, rural and urban, were initiated and conducted and how they have succeeded in their purpose of discovering, examining and making educational provision for children with permanently impaired hearing, or having ear and throat conditions pointing to impaired hearing if neglected. Referring back to the committee's announcement in a previous issue of this journal (February 1, 1934) let it be understood that the children under consideration are not deaf (anacusis, having no hearing), deaf children being few in number and presenting, comparatively speaking, a problem which is mainly educational but which in some of its aspects is receiving the attention of this committee. The committee's preoccupation with the child who is beginning to lose his hearing is a reasonable one; first, because there are many such children in our public schools; second, because the probabilities for successful preventive work are great. Beginnings have been made and it is the purpose of this and succeeding articles to describe several which may be observed within the boundaries of this State.

Work in this field of conservation of hearing requires a certain psychological approach on the part of the physician, nurse, teacher or social worker. For untold ages any defect in hearing power, no matter how slight, has been approached, psychologically speaking, through the concept deaf—*anakousia*, no hearing. Conservation of hearing approaches the hearing impairment from the opposite quarter, as something which has dropped from the norm—*hypoakousia*, less hearing—but which is not by any means a conclusive condition. It is, in fact, one which possesses strongly hopeful elements. Early discovery may lead to medical amelioration and certainly to

study the two projects now functioning in Westchester County.

The rural project, although the younger, will be given precedence. This hearing survey of the Second Supervisory District of Westchester County was conducted in April and May, 1933, by Mrs. Eleanor Ronnei, teacher of lip reading and speech correction in the Valhalla public schools. Mrs. Ronnei, who is an active member of the Lip Reading Teachers Auxiliary of The New York League for the Hard of Hearing, first enlisted the interest of the school nurses of the district, who in turn consulted the various school physicians. The latter proved cordially cooperative and their permission was received before any further steps were taken. The League loaned two of its audiometers, both the 4A and the 2A, Mrs. Ronnei loaded them into her car and set forth among the small communities of the district. Two thousand two hundred eighty-five elementary school children from the third year on were tested with the 4A audiometer in eight villages: Armonk, Briarcliff Manor, Hawthorne, Pocantico Hills, Purchase, Thornwood, Tuckahoe and Valhalla. Retest was then made with the 2A audiometer of 124 children whose 4A audiograms indicated poor hearing. Otological examination of these children was the next step. There are no specialists in this rural district, so Mrs. Ronnei sought the cooperation of Dr. J. R. Emery of White Plains. Dr. Emery was already familiar with the school hearing program developed by The New York League for the Hard of Hearing, as he had worked in the League's clinic at Manhattan Eye, Ear and Throat Hospital under Dr. Edmund Prince Fowler, Director of Research and Clinics of the League. He generously gave time and services; Mrs. Ronnei drove him among the villages and in six of them 101 children received otological examination. Here is the statistical report of the survey:

Village	Total exam.	IHB	IHR	IHL	Retest	History	Examined Otologist	Definite L R cases	L R cases pending	Otological and retests
	4A	4A	4A	4A	2A					
Armonk	135	9	3	8	6	21	4	2	4	0
Briarcliff Manor	302	13	21	22	7	137	0	1	4	2
Hawthorne	158	11	5	9	10	76	4	4	4	0
Pocantico Hills	95	5	3	2	8	19	6	4	4	0

educational as well as psychological compensations. Again, we can get much farther with educators, teachers, family doctors and above all, with parents, if we use this approach and point the way to hope. Let us avoid the zero, deaf, and keep good hearing, better hearing, conservation of hearing, hopefully before our minds as we

This survey so keenly interested District Superintendent Cheney that he is now endeavoring to interest the villages of Armonk, Hawthorne, Pocantico Hills, Thornwood and Valhalla in the joint purchase of their own 4A audiometer. This will make possible the annual survey which is generally advocated as part of the regular

school health program, not only for the five villages named, but also for the nearest smaller communities, fourteen in all.

The Valhalla lip reading teacher, Mrs. Ronnei, is instructing some of the children in lip reading. Three villages, Hawthorne, Pocantico Hills and Tuckahoe, are awaiting at present the decision of the State Department of Education regarding a grant to cover a teacher's salary. The itinerant teacher plan seems to be the most practical way to provide lip reading and at the same time keep the children in their natural school environment among their normally hearing schoolfellows, a condition which is of the utmost importance to the normal psychological development of these hard of hearing children, who, after all, are normal children. Their slight hearing loss is no greater handicap, when they have received instruction in lip reading, than myopia or astigmatism when corrected by suitable glasses, and much less of a handicap than cardiac lesions or rickets, since they are able to profit fully from active competition in the playground as well as in the classroom. Segregation of such children is not desirable or necessary and is considered injurious to development of a normal personality with which to

Other includes ster County which have been sur. Dr. Emily A. Pratt, bureau, State Department of Education, has also surveyed or loaned an audiometer for surveys in Hartsdale and Greenburg, and we believe also in Yorktown Heights, Pleasantville and Portchester. There is undoubtedly a great field for work in conservation of hearing among the central Westchester villages.

White Plains, as befits the county seat, first introduced conservation of hearing into its schools, to be followed by Ossining-on-Hudson, where the school physician, Dr. M. Mary Rohn, has set up the routine of surveys, retests, examination and lip reading. In White Plains, where the school enrollment is about 7000, Dr. Dorothy Worthington, also a school physician, made a study of the subject in 1929. She interested the school board and the local otologists, a 4A audiometer was purchased and surveys were begun. She then consulted the New York League for the Hard of Hearing, from which she had received her initial information, regarding a lip reading teacher and the League recommended Mrs. Alice Howe Hatton, who began work in March, 1930. Mrs. Hatton has the distinction, although still a young woman, of being the pioneer in lip reading instruction for the hard of hearing child, her first work in this field having been done in the Rochester public schools from 1916 to 1924.

Again the itinerant teacher plan seemed the only practical way to teach lip reading to the twenty-five children who had been tested, retested and examined, as they were located in four different sections of the city. In order to reach them for two periods a week, Mrs. Hatton made use of her own car, driving from school to school. Among these children were several whose im-

paired hearing had made them distinct school problems both academically and in social adjustment. Within three months their teachers were enthusiastically reporting improvement on both counts. The four groups have been brought together for annual contests and demonstrations before audiences of school nurses, physicians, mothers and school officials.

An annual program has been adopted which provides for hearing tests for one-half of the schools (elementary and junior high) with examination of all third grades, new pupils and children previously found to have hearing losses, every year or oftener. Testing is done and also correction of papers by the school nurse and the lip reading teacher. They are deeply conscious of the fact that the retest with 2A audiometer should precede the otological examination, but this essential equipment has not yet been purchased and audiograms cannot be made. There is hope that a 2A will be made available. The otological examination is considered part of the regular school health examination, and the White Plains school health record card pays due attention to hearing and to the lip reading department.

Examination began with one physician, and has increased to four. Some of the children are examined by private physicians, but the majority of the examinations are done in the school nurse's office and if the parents are not present a full report is sent to the home. Early in 1933 the White Plains Hospital opened an Ear, Nose and Throat Clinic, where some remarkable work has been done with acute cases. There is fine co-operation between the clinic and the school nurses, but for all that there are many difficulties. Many children are too poor to pay the clinic fee and this necessitates a visit to the Welfare Department before going for treatment. The clinic is overcrowded. Parents are frequently uncooperative, and not only must their outlook be changed but also that of the family doctor upon whose opinion they place implicit reliance. The latter frequently does not realize that small ear trouble . . . of developing into . . . social problems. Bette: . . . and coordination . . . clear up these administrative difficulties, give the White Plains hard of hearing children the 2A retests and clinical service they need, teach the parents the importance of good hearing and at the same time enlist the moral support and active aid of the general practitioner. The statistics follow:

Hearing Tests in White Plains Schools	1931-32	1932-33	1933-34
Tested by 4A audiometer..	2589	2824	1207
Retested (4A)	89	671
Potential cases	116	214	218
Referred for ear examinations	(4.48%)	(7.57%)	184
Otological examinations ...	17	30	28
Impacted cerumen cases...	18	77	47
Needing treatment	80	61
T & A removed	28	59	38
Recommended for lip reading			

480 LEXINGTON AVENUE

A weekly diet costing 5s 10½d (about \$1.50) as a minimum for adults has been unanimously approved by the Council of the British Medical Association. It provides 3,400 calories and

50 gm. of first-class protein daily. Too much! said the Government Ministry of Health, which declared a daily total of 3,000 calories and 37 gm., costing about \$1.20 a week, sufficient.

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

CHARITABLE HOSPITALS—EXEMPTION FROM LIABILITY FOR NEGLIGENCE OF NURSE

An excellent example of the application of the rule which ordinarily exempts a hospital, organized not for profit, from liability for negligence, is shown in an interesting case recently decided in one of the mid-Western States. The case was one in which the suit was based upon an unfortunate incident in connection with a mistake as to the identity of two babies.

A certain man named G., brought his wife and their week-old baby to the hospital in question to be cared for. Some days later the wife died and the husband took the body of his wife to another city for burial. He made arrangements meanwhile with the hospital that he should pay a dollar a day to the hospital, and was assured that the baby could remain there and receive the best of care. At about the time of the birth of the child so left in charge of the hospital, the daughter of a certain V. had given birth at the same hospital to a child. That child was the issue of an incestuous relationship between Mr. V. and his daughter. When the daughter was ready to leave the hospital, she also arranged to leave her child behind. V. called at the hospital to get his baby and through the carelessness of one of the nurses, the wrong baby was given him, and he received the child of the first man. The nurse had confused the two men and had thought she was delivering the baby to G. When G. called for his child he was offered the other baby and the mistake was discovered. Efforts were made to right the mistake but the G. baby was not recovered. It seemed that V. had disposed of the child in some manner, his story when questioned about it being that he had given the child to some strangers who had passed through the town in an automobile.

The father of the missing child brought an action against the hospital, charging it with both negligence and breach of contract. It was unquestioned that the hospital was a corporation organized under the laws of the State as a nonprofit institution. Upon the trial there was very little dispute as to the facts. Unquestionably the nurse

had been negligent, but the Trial Court would not permit the hospital to be held responsible for her negligence. The plaintiff attempted to show that the hospital had been negligent in hiring the nurse, but failed for proof was put upon the record that the nurse whose wrongful act was the basis of the action was properly qualified. When the act occurred, she had been in the hospital's employ as a registered nurse for some three years, and prior to that she had had three years' additional hospital training. Upon the trial the plaintiff recognized that he could not possibly hold the hospital, a nonprofit organization, for the negligence of its servants and discontinued the action so far as brought on a theory of negligence. The plaintiff, however, sought to hold the hospital on the theory that the hospital had expressly contracted to care for the baby at a stipulated fee, and to return it to the plaintiff when called for, and that it had breached the terms of said contract. The Trial Court denied recovery upon the said theory, applying the same rule of exemption as in an ordinary tort case. The plaintiff also sought to show, as a means of circumventing the application of the charitable-hospital rule, that the defendant hospital carried liability insurance, contending that if insured against loss the reasons for exempting the hospital from liability should not be applied. Such proof was excluded as improper. Judgment was entered in favor of the hospital.

An appeal was taken to the Appellate Court of the State, and that Court after careful consideration, affirmed in all respects the ruling of the lower Court. It found that the grievance of the plaintiff actually was based on a negligent act, and that the law of negligence should be applied regardless of how he had technically designated his action. It said:

"Naming or labeling a count *assumpsit* (contract) does not make it such, when it is apparent on its face that it is one in tort. Nor is there any magic in the use of one term instead of another, when the gravamen of the act complained of is the negligence or mistake of a

servant of an eleemosynary institution exempted from liability by law under these circumstances.

The Court quoted the principles behind the so called Charitable-Hospital Rule as follows

If the contention of the learned counsel for the plaintiff be true, it follows that the charity or trust fund must be used to compensate injured parties for the negligence of the trustees or architects and builders, upon whose judgment reliance is placed as to plans and strength of materials, of physicians employed to treat patients, and of nurses and attendants. In this way the trust fund might be entirely destroyed and diverted from the purpose for which the donor gave it. Charitable bequests cannot thus be thwarted by negligence for which the donor is in no manner responsible. If in the proper execution of the trust, a trustee or an employee commits an act of negligence he may be held for his negligent act, but the law jealously guards the charitable trust fund and does not permit it to be frittered away by the negligent acts of those employed in its execution. The trustees of this fund could not by their own direct act divert it from the purpose for which it was given or for which the act of the legislature authorized the title to be vested in the defendant. It certainly follows that the fund cannot be indirectly diverted by the tortious or negligent acts of the managers of the fund, or their employees though such acts result in damage to an innocent beneficiary. Those voluntarily accepting the benefit of the charity accept it upon this condition.

The fact that patients who are able to pay are required to do so does not deprive the defendant of its eleemosynary character, nor permit a recovery for damages on account of the existence of contract relations. The amounts thus received are not for private gain, but contribute to the more effectual accomplishment of the purpose for which the charity was founded. The wrongdoer, in a case of injury, but not the trust fund, must respond in damages. This proposition seems too clear to require argument or authority. It is not, however, inappropriate to remark that better facilities for the care, cure and treatment of the sick, both of the poor and of those who are able to pay, are secured by the establishment of hospitals like that of the defendant. These facilities are increased by the receipt of money from those who are able to pay in whole or in part for the benefits received. Several hospitals of this character exist in this state founded by private munificence. Obviously, they would not have been founded if their donors had known or ever supposed that their charitable purposes might be thwarted by the verdicts of juries for the negligent acts of those who must necessarily be employed in the execution of the charity.

The Court in its opinion also referred to a case that was decided in New York State some years ago, in which an attempt was made to hold a charitable hospital liable in damages arising out of an alleged breach of contract. The charge there was that the hospital had agreed to keep a constant and continuous watch over an insane patient, and failed to keep such watch,

whereby the patient threw herself from the window and was killed. The New York Court denied liability and said

But the contract was to keep a constant watch and guard. It was not to prevent the unfortunate patient from committing suicide. Nor could it fairly be held to be within the reasonable intendment of this contract that the hospital agreed to pay to the husband the value of his wife's life to him in case she did commit suicide. There has been no case cited to us nor have we been able to find one which allows a recovery upon such a complaint or such a state of facts. Nor can we see any reason why there should be a different rule where the tortious act which caused death is alleged to be a breach of an express contract from that declared where it is alleged to be a breach of an implied contract or where no contractual relation at all existed.

Claim of Negligence in Tracheloplasty

A doctor who had for many years specialized in surgery was called to the home of a married woman about 35 years of age. She complained of having suffered pain for about two weeks and gave a history of persistent discharge from the vagina.

After a physical examination, the doctor made a diagnosis of eroded bilateral lacerated cystic cervix, slightly relaxed perineum, and an acute attack of endocervicitis. He recommended an operation and two days later performed it.

The doctor made a cone-shaped incision of the cervix and after separating the cervix from the vaginal mucous membrane, excised the infected tissue. The mucous membrane was then sutured to the cervical mucosa following the technic of Sturmdorff. The cervix and vagina were then packed with gauze and the patient returned to her bed.

The surgeon took charge of the post-operative care of the patient and removed the packing 60 hours after the operation. No untoward complications developed in the case until nine days after the operation at which time she expelled a clot of blood and the wound was packed by the house surgeon. The following morning the doctor in charge of the case found her condition to be satisfactory. He removed the packing and there was no further bleeding.

A week later she was discharged from the hospital. At the time of the discharge the doctor did not examine her vaginally for fear of setting up an infection or hemorrhage.

A lawsuit was thereafter instituted against the surgeon, claiming that the operation which he performed was done neg-

ligently and that it was subsequently necessary as a result of his operation for the patient to undergo another operation for the removal of her uterus. The case came on for trial and the medical witnesses who took the stand on behalf of the plaintiff failed to establish that the defendant's operation necessitated the subsequent removal of the patient's uterus, for it came out that the actual cause for the subsequent operation was a tumor which later developed. The case, however, was sent to the jury to determine the truth or falsity of the plaintiff's story that certain gauze packings had remained in the uterus and vagina several days longer than proper and whether the woman was discharged from the hospital by the defendant while she was suffering from a hemorrhage.

The jury returned a verdict in favor of the defendant, thereby rejecting the testimony of the plaintiff and her witnesses and exonerating the defendant from all charges of malpractice.

Claim of Negligence in Connection With Use of Lane Plate

A man about 32 years of age was assaulted by ruffians and was found unconscious and taken to a municipal hospital where examination showed that he had a fracture of the right leg just above the ankle. His injuries were treated and the leg put in a plaster cast. Upon his return to consciousness he suffered continuous pain and after about two weeks he was transferred to another hospital and the care of a certain specialist in surgery.

The said doctor caused an x-ray examination to be made of the limb and found a fracture of the right tibia and fibula about 4 inches above the ankle joint with the fragments displaced outward and backward and about one inch overriding. He undertook to reduce the fracture and to secure a satisfactory alignment by a closed method, but because of the length of time that had elapsed since the injuries were sustained the doctor was unable to accomplish his purpose.

A few days later he had the patient put under a general anesthetic and made an incision over the lower third of the fibula in the region of the fracture. The bones were placed in correct apposition and a Lane plate with four screws was inserted. Plaster splints were applied, and x-rays taken after the operation showed that the

position of the fragments continued to be good. Subsequent x-rays were taken thereafter from time to time until about ten weeks after the operation, when the doctor decided that callous having formed the Lane plate had served its purpose; therefore he performed an additional operation and removed the plate from the tibia.

The patient's leg was placed in a cast and was treated by the doctor regularly for a period of about three months during which time the man's condition improved very well. At about the time he was to be discharged he suddenly developed a pain in the region of his knee. The cast was removed and the knee found to be swollen. Wet dressings were applied to this region, and a few days later the doctor aspirated the knee joint and found pus. He made an incision on both sides of the knee introducing a tube for drainage. The wound continued to drain and the knee cavity was syringed daily, this treatment continuing for several weeks. During this time the doctor decided that in order to obtain proper drainage it was necessary for the knee to be held in a flexed position with the leg at almost right angles with the femur. During the period of time in which the knee was held in such a position, little progress was made in passive motion to prevent ankylosis by reason of the great pain which it caused the patient. The inflammation and infection finally subsided after a total period of hospitalization of over a year. At the end of that time the patient was discharged from the hospital by the doctor and advised to go to another hospital for baking treatment to alleviate the condition of ankylosis which had developed. The patient apparently sustained as an end result considerable loss of motion in the knee.

An action was instituted against the doctor charging him with malpractice in connection with his treatment of the patient and specifically making the claim that the introduction of the Lane plate and its subsequent removal were the cause of the prolonged period of hospitalization and of the man's loss of the use of his leg. The action finally came on for trial before a judge sitting without a jury and at the close of all the testimony introduced the court ruled that the plaintiff had failed to prove that the treatment rendered by the defendant had been in any respect improper and therefore directed judgment to be entered in favor of the doctor.

Books

BOOKS RECEIVED

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

A System of Clinical Medicine Dealing with the diagnosis, prognosis, and treatment of disease for students and practitioners. By Thomas Dixon Savill, M.D. Ninth Edition. Octavo of 1063 pages illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$9.00.

A Synopsis of Surgery By Ernest W. Hey Groves, Tenth Edition. 16mo of 693 pages. Baltimore, William Wood & Company, 1933. Cloth \$5.00.

Human Embryology and Morphology By Sir Arthur Keith. Fifth Edition. Octavo of 558 pages illustrated. Baltimore, William Wood & Company, 1933. Cloth \$10.00.

Neuroanatomy A Guide for the Study of the Form and Internal Structure of the Brain and Spinal Cord. By J. H. Globus, M.D. Sixth Edition. Quarto of 240 pages illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$3.50.

Food and the Principles of Dietetics By Robert Hutchison M.D. and V. H. Mottram, M.A. Octavo of 630 pages. Baltimore, William Wood & Company, 1933. Cloth, \$7.25.

Life Giving Light By Charles Sheard Ph.D. 12mo of 174 pages, illustrated. Baltimore, Williams & Wilkins Company, 1933. Cloth, \$1.00.

The Medical Clinics of North America. Volume 17, No. 4, January, 1934. (Cleveland Clinic Number.) Published every other month by the W. B. Saunders Company. Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.

Influenza By David Thomson and Robert Thomson. Quarto of 640 pages illustrated. Baltimore. Williams & Wilkins, 1933. (Volume IX December 1933 of *Annals of the Pickett Thomson Research Laboratory*, Monograph XVI, Part 1.)

BOOKS REVIEWED

Starling's Principles of Human Physiology Sixth Edition, edited by C. Lovatt Evans, D.Sc. Octavo of 1122 pages illustrated. Phila., Lea & Febiger, 1933. Cloth, \$8.75.

The manner of presentation, the general handling and the subdivisional arrangement of subject matter are quite the same in this sixth as in the fifth edition of Starling's Well known *Principles of Human Physiology*. Comparative page to page perusal of the two editions, however, clearly indicates painstaking revision of its text throughout. Some shifting of paragraphs and sub sections, many verbal changes and judicious incorporation of subsequently developed material afford abundant evidence of the editor's successful endeavor "to keep its contents representative" without undesirable enlargement of the book, the bulk of which has been but slightly increased. The illustrations, too, have been reviewed with regard to the requirements of the revised text, a few having been eliminated, but a sufficient number added to increase the total by nineteen. What has been said of the volume as a whole, under the editorship of Professor Evans, applies specifically to its Book III, *The Central Nervous System and Special Senses*, which makes up nearly a quarter of the volume and for the excellence of which Professor Hart-ridge deserves commendation. The general satisfaction of this sixth edition assures continuance of the widely appreciated value of the book as an aid in the scientific teaching of human physiology.

J. C. CARDWELL

Maternal Mortality in New York City A Study of all Puerperal Deaths, 1930-1932. By the New York Academy of Medicine Committee on Public Health Relations. Ransom S. Hooker, M.D., Director of Study. Octavo of 290 pages. New York, The Commonwealth Fund, 1933. Cloth, \$2.00.

This is an honest interpretation of a large group of figures traced from every angle. The difficulty in reading and studying such an enormous number of statistics is admirably overcome by the interesting text. The matter divulged

seems to be an indictment against physicians and places upon their shoulders most of the responsibility for the end results.

However, a more careful analysis reveals that the bulk of obstetrics in New York City is done by physicians and of necessity they are obliged to handle some of the greatest obstetrical problems.

They know conclusively where improvements can be made and if their recommendations are followed, better results are bound to come.

This volume should be read by every one practicing obstetrics.

WILLIAM C. MEAGHER

Behind the Doctor By Logan Clendenning, M.D. Octavo of 458 pp illus. N. Y., A. A. Knopf, 1933. Cloth, \$3.75.

Clendenning has already won fame with his "Human Body." His second attempt "The Care and Feeding of Adults" was for some unknown reason quite eclipsed by his initial undertaking in the lay field.

And now we are greeted with "Behind the Doctor." Clendenning is more imaginative in this work and lives successfully in different ages of medical history. Instead of confining himself to detailed reports he takes part in the enlightening conversations of these pioneers. The numerous illustrations in this book are in general more interesting than in his first book. One feels his enthusiasm in every page.

EMANUEL KRIMSKY

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 4, 43rd Series 1933. Edited by Louis Hamman, M.D. Octavo of 317 pages. Philadelphia, J. B. Lippincott Company, 1933. Cloth, \$3.00.

In the first article, Wilder outlines the treatment of obesity used by him which is based upon the method previously described by Strang and his associates. The author, however, allows more carbohydrates—about 500 or 600 calories

in all; instead of the 360 allowed by Strang—and he uses yeast vitamin tablets instead of the actively growing yeast for vitamin B. He uses dibasic calcium phosphate to prevent mineral deficiency. For vitamins A and D, a concentrate of cod liver oil in tablet form has been used. Thyroid is used only on rare occasions.

Other articles deal with Acromegaly, Hypertension, and the Serum Treatment of Pneumonia. In the latter account Finland brings the subject up to date in all particulars. There is a section on the use of endocrine-gland products in the treatment of disease, among the writers being Campbell, Rowntree and Novak. There are also sections on Surgery, Clinical Pathology, and Dermatology.

It is an excellent number and a very useful book to have at hand.

W. E. McCOLLOM

Colds and Hay Fever. By Frank Coke, F.R.C.S. 12mo. of 148 pages. Baltimore, William Wood & Company, 1933. Cloth, \$2.00.

This small book deals with the various conditions in which sneezing is the most prominent symptom. It is written in an attempt to aid the practitioner in the differential diagnosis and treatment of these illnesses.

The author presents some of his own theories regarding the mechanism and treatment of these diseases. He admits that his theories are not based upon experimental evidence, but upon personal impressions, and that they need corroboration. The methods of treatment outlined are not entirely original, but are mostly applications of procedures introduced by others. His enthusiasm for certain forms of nonspecific therapy has not generally been shared by other workers. This book, however, makes interest-

ing reading concerning a symptom not commonly dealt with at such length in other works.

MATTHEW WALZER

A Practical Medical Dictionary. By Thomas Lathrop Stedman, M.D. Twelfth Edition. Octavo of 1256 pages, illustrated. Baltimore, William Wood & Company, 1933. Fabrikoid, \$7.50.

Stedman's Medical Dictionary is, in the opinion of this reviewer, the best. We have come across no blunders in this edition, either in spelling or in definition. The general arrangement is clear and convenient. It is used in our office in preference to the several other dictionaries remaining on our shelves.

FREDERIC DAMRAU

Record-Librarian's Manual. A Guide to Organizing, Classifying and Filing Clinical Records and Medical Literature. By Carl E. Black, M.D. Octavo of 154 pages. St. Paul, Minn., Bruce Publishing Company, 1933. Cloth, \$2.00.

This work presents a modified expansion of the Dewey Decimal classification with form divisions, using anatomy as the basis of classification. This system has been in use for twenty years and yet the author does not claim it to be the only worthwhile one.

The book is divided into three parts: Instructions to Record librarians, Outline and Expansion of Dewey Classification, and Index to Classification. While all parts are necessary, the index will be especially useful when the rest of the book has been mastered.

A new book in a comparatively new field. The record librarian may easily adapt it to whatever system happens to be used in his or her hospital.

WESLEY DRAPER

TO BE SUCCESSFUL

The following prescriptions for success appear in *The New England Journal of Medicine*. Are they correct? Perhaps some of our readers, out of their experience, can add other don'ts and do's, or criticize the ones now in the list. Here they are. What do you think of them.

Family Physician:

Don't treat something you do not understand without expert advice.

Don't fail to be frank with your patients.

Don't fail to talk their language.

Don't fail to write out instructions.

Don't fail to consult the nurse on the case.

Don't talk shop to patients.

Don't tell patients how good you are.

Don't fail to have outside interests.

Don't have financial dealings with patients.

Don't keep moving from town to town. Select your location carefully and then stick.

Don't fail to show the spirit of service.

Practice:

Firmness, fairness, and frankness with the patient, but do not show temper.

Accompany the patient to the specialist's when possible. A personal introduction goes a long way and the specialist would benefit greatly by the added conference with you while on the case.

Be neat and clean in your personal appearance.

Give more time to the convalescent stage of the disease.

Show cheerfulness and encouragement in your work.

Be fair to your professional rivals.

Specialist:

Don't work alone. Find out who the family physician is when possible.

Don't fail to have close contact with the family physician.

Don't omit the written reports to the physician.

Don't disregard the patient's story.

Don't protect the family physician when gross negligence is evident.

Don't necessarily form conclusive opinion on single visit evidence.

Don't object to a second opinion in obscure cases.

Don't overcharge.

Don't fail to show the spirit of service.

Be considerate of patients and family's reactions to your opinions. Select your words with care.

During an extended examination observe carefully the patient's condition, lest a too fatiguing conference be held.

Don't send patients home from office operation on the elevated when they request a taxi.

MEDICAL SOCIETY OF THE STATE OF NEW YORK
ANNUAL REPORTS, 1933-1934**REPORT OF THE PRESIDENT**

To the House of Delegates:

Gentlemen:

It is needless for me to state that at the present time there are more changes occurring in our methods of practice, our relations to the public and its institutions than have arisen since the time this Society was founded. Medical economics are discussed in every group of physicians where more than two or three are gathered. Every Medical Society has its discussions. Every State and National Journal, representing organized groups, is publishing paper upon paper on the subject. Hospitals and dispensaries are accused of infringing upon the rights of the physician. Out-patient departments, it is claimed, are treating many individuals amply able to pay the physician. The hospital, as a corporation, is accused of practicing medicine—for example, the permitting of a department, such as the x-ray department, to treat outside private patients, make a diagnosis, charge a fee for such service and pay the physician on a salary basis thereby becoming an unfair competitor of the physician who, at considerable expense, has prepared and equipped himself for this service. Large medical centers with their great organizations are receiving considerable criticism from the profession. They, also, often disregard the ability of the patient to pay and accept many cases in free wards, who are amply able to pay, in order that they may fill their beds and carry needed "clinical material." This same criticism is made against the municipal hospitals in allowing the well-to-do free service and free hospitalization.

In the "new deal," which our present administration is endeavoring to put over, unfair competition in business, in trades

and in all activities of the public, is to be eliminated. The working of the Compensation Law has received its share of criticism in its discrimination. Lay organizations are believed to be interfering with certain functions of the practice of medicine in their efforts to socialize medical activities. The Health Departments are accused of practicing medicine. The State is accused of unfairness in its methods of handling the compensation care of the indigent. Wherever one goes, there is a spirit of unrest.

The Committee on Economics has been studying and investigating these and many other problems. Our Legislative Committee has been constantly on the alert to head off any legislative bills that would react unfavorably. Our Public Relations Committee is doing its share in solving these questions. The minority of the Committee on the High Cost of Medical Care rendered an excellent report which appears to have had a wholesome effect.

It is quite apparent we have made considerable progress this past year. Many clinics have taken measures to eliminate the individual, who is able to pay, from receiving free service. It may not be apparent in some sections but in many localities there has been definite improvement. The change, which Dr. Goldwater brought about in New York City whereby the city-owned hospitals can no longer care for compensation cases and receive for surgical services the fees which should go to the physician, is a bright spot on the horizon. Would that there were more Dr. Goldwaters in our profession with similar power for change.

It is the function of the State to protect the public. The Health Department is

called upon, where life and death are involved, to perform this function. In 1833 our Society went on record by petitioning the Legislature to establish a vaccine institute at Albany so that a pure vaccine might be furnished the profession for the prevention of smallpox. I take it this was the first effort of our Society to ask the State to give us a pure biological product for the prevention of disease. As a result of this early Act of the Legislature, the seed was sown which has grown into what, at the present time, is the Biological Division of the State Health Department with its vaccine serums and many other products which it furnishes to the physician gratuitously or at a nominal cost. This service from the State has enabled many physicians to save lives which otherwise would have been sacrificed.

At times the activities of the Health Department may appear to encroach upon the rights of the private physician. It is gratifying to note the policy of the health authorities to cooperate with and adjust the differences which necessarily must arise from their contacts with the profession.

The same group of the early members of our Society, who advocated a pure vaccine at the meeting of 1833, petitioned the Legislature to establish an institute located in the center of the State for the care of the insane. It was estimated at that time there were about 3000 indigent insane in the State. This was the beginning of our great system of institutions for the care of the mental case. This system has grown to the extent that the State paid \$23,000,000 for this one activity during the past fiscal year. The State and Counties have largely taken over the care of the tuberculous patient.

There are many medical activities which the State, in protecting the citizen, must perform. On the other hand, there are many functions which the family physician should be given the privilege of performing—examination of school children, the administration of toxin antitoxin, vaccination and many other like activities. The control of syphilis with its present highly technical treatment should be placed in the hands of those who are properly trained and equipped to care for such cases. The great number of uncured cases in every community with their serious sequelae, which become a burden on the public and add greatly to the census of our insane

institutions, is sufficient argument.

There is a definite effort by certain well-meaning laymen to establish socialized medicine in this country. We are familiar with what socialized medicine means to Russia and Germany. It would require another revolution in Germany to place the medical practice back on the high level it enjoyed before the present regime. It is argued by certain advocates that the practice of medicine is comparable to the profession of teaching. God forbid! The school teachers have suffered enough through this depression with thousands of them going unpaid in many diverse localities. In a recent Literary Digest it was stated that 200,000 teachers in the schools, which represent 25 per cent of all the teachers in the country, received \$750 or less per year. On this basis they received an average weekly income of \$15.00 per week which is less than the average CWA worker was receiving. In addition to this 85,000 teachers received less than \$500 per year or \$9.00 or less per week. This is what a socialized group of educated people are paid. Socialization of medicine may come. If it must occur, let it be such that it will elevate the practice of medicine and not lower our present standards. It is up to every member of our profession to take a definite stand on this question.

The Public Relations Committee has held conferences in various sections of the State this past year. I have had the pleasure of attending two such conferences. Their work in ironing out misunderstandings in at least two of our State Aid Hospitals deserves special mention. The work of this Committee has produced a feeling of harmony which is quite apparent in the various sections of the Medical Society of the State of New York.

The Committee on Economics in 1932-1933 evolved many excellent ideas whereby the Workmen's Compensation Law could be improved. They reported to the 1933 house of Delegates and suggested many changes in the Law. Governor Lehman in 1933 requested that a Committee be recommended to him which would study the present Compensation Law and make recommendations that would correct many of the abuses existing in the present Law. The Governor appointed five members from the Academy of Medicine of New York City and five from the Medical Society of the State of New York. These ten physicians have had many sessions and

devoted a great amount of study on the problem. Their report speaks for itself. If their recommendations are placed in the Law, the Compensation Law in the State of New York will be greatly improved and will be a model for other states.

The work of our Committee on Public Health and Medical Education cannot be appreciated unless one comes in contact with its working. It has been my privilege to attend some of the lectures. The high type of men our Chairman has been able to secure to give these lectures on practical subjects has been very gratifying. The enthusiasm of the men attending and the good attendance speak for themselves. As I have gone about the State this year, there appears to be a real demand for more of these courses.

The Legislative Committee has, as usual, rendered valuable service in heading off bills which were undesirable for the cause of scientific medicine and the welfare of our profession and the public. They have given their best efforts to promote desirable legislation. We owe a great debt to this Committee for what it has accomplished.

Our scientific program has been carefully arranged by the Chairman and his associates. Several new features are being introduced which bid fair to make our meeting one of the most interesting and scientific that you have ever attended. The new Chairman has given considerable time and study to his program. Let everyone, who attends the Utica meeting this year, make an extra effort not only to attend but take part in the discussion of the scientific program.

It is apparent, as I have visited various County and District Branch Societies, that organized medicine in New York State could be greatly improved if every County Society could be so organized that a meeting be held at least each month during the year excepting in June, July and August. This would stimulate more interest in the program and work of the Society. That every Society should appoint one or more of its members to serve on a County Committee which would represent the Public Health; one or more members who would serve on the Scientific Program; one or more members to represent Public Relations; one or more members to represent Legislative activities and one or more to study the Economic situation. These are the five Standing Committees which con-

sider the plans and policies of the State Society. If each County Society would do this, a different spirit would exist with more interest in the activities of the state organization.

Our Executive Officer has innumerable duties to perform. It is impossible for him to attend all the committee meetings, special and standing, attend the District Branch meetings, attend to the active legislative work which arises each year and visit all the County Societies. It has been my privilege this past year to observe all the demands that are made on him in his service to the State Society. It occurs to me that a field secretary might be appointed who would contact and visit the County Societies and point out to them how they can improve their organizations so that they could be an active part of the Medical Society of the State of New York.

There is a feeling among certain County Societies that our dues are a burden. I must again call your attention to the fact that, whatever the County Society dues may be, the State Society receives \$10.00 from each member. The \$10.00 you pay gives a directory to each member in the state with enough information concerning each member to enable you to know where and when he was graduated, his special work and his hospital connections. You receive a Journal twice each month which, if you take the time to read it, is worth its cost. It keeps you in touch with the various activities of the State Society. Every member in good standing has legal protection and counsel by a high grade attorney in case you are sued for malpractice. This service alone is worth what is paid. It does not furnish indemnity in case of a verdict. Those, who desire to protect themselves in case of a verdict, must insure in our designated insurance company.

I wish to take this opportunity to acknowledge the services of Secretary, Dr. Daniel S. Dougherty, who keeps the machinery of our Society oiled and running smoothly and to Dr. Peter Irving, our Assistant Secretary, to whom we are greatly indebted for looking after the affairs during the illness of our Secretary; also, the aid which Miss Baldwin, with her long experience in the affairs of the Medical Society of the State of New York, has rendered me during my term as President.

Respectfully submitted,

FREDERICK H. FLAHERTY, *President.*

April 1, 1934.

REPORT OF THE SECRETARY

To the House of Delegates:

Gentlemen:

Your Secretary has the honor of submitting his ninth annual report.

THE SOCIETY

It gives him pleasure to report a steady progress and growth in membership and in activities.

As usual the report is administrative rather than clerical. But one event of any great importance is to be recorded, the change in the publication and management of the JOURNAL, a detailed report of which will be given under the appropriate heading.

THE SOCIETY'S OFFICES

For the first time in ten years a change has to be recorded. Through the giving up of the JOURNAL offices the Executive Editor, the Advertising Manager and the two stenographers necessarily lost their connection with the Society.

The Secretary is pleased to record, however, that Dr. Overton is now Editor of the *New Jersey State Journal* and the contract of Mr. Tufts has been taken over by the new business management.

The personnel of the Secretary's office is constituted of the same willing and efficient staff that it has been for several years past. This includes, of course, Miss Baldwin, the Office Manager without whose intelligent grasp of the Society's affairs both past and present, your Secretary would feel a severe loss. Mrs. Roetger, the Assistant Manager, and Miss Briggs in the Legislative office at Albany, deserve more than passing notice.

FINANCIAL DEPARTMENT

A study of the statements of the Board of Trustees and of the Treasurer shows that despite the depression the Society has suffered but little. An astonishing fact is that many county societies have raised their dues, showing a realization of the importance to them of organized medicine.

The personal worth of our Trustees has been proven by the action of the House of Delegates of the American Medical Association in electing Dr. Arthur Booth a trustee of that body and Dr. N. D. Van

Etten Vice-Speaker of its House of Delegates.

LEGAL DEPARTMENT

Under the able guidance of Mr. Lorenz J. Brosnan as Counsel and Mr. T. H. Clearwater as Attorney, the legal affairs of the Society in regard to the malpractice defense of its members as well as the advice requested by officers and committees has been well taken care of.

Attention is called to the following resolution adopted several years ago which has at times been a matter of disturbance to your counsel and secretary:

"All questions or requests for information by committees or county societies or individuals must be referred, therefore, through the Secretary's office to the Executive Committee with which Counsel sits."

When your Secretary introduced this resolution it was not realized that there were times when two or three months might elapse between the receipt of the request and the meeting of the Executive Committee. He therefore recommends with the concurrence of Counsel that all such questions or requests that might be in the emergent class be taken up by Counsel with the Secretary.

The Secretary acknowledges with thanks the many acts of kindness and the valuable advice given in conducting his correspondence.

RETIRED MEMBERSHIP

Your Secretary feels that an injustice is being done to this class of members, many of whom are still practicing and therefore liable to malpractice suits.

He recommends that the right to malpractice defense and the privilege of insurance be granted to them.

COMMITTEES

The work of the committees, both standing and special, has been performed cheerfully and willingly and the Secretary feels that he can voice the appreciation of the Society in the excellence of the work and the loyalty shown to the ideals of the Society and the profession by the members.

He extends his personal thanks to the Chairmen of the standing committees who have recognized his membership in them by extending invitations to their meetings.

It is with no intention of putting a greater burden on them but because of this loyalty and experience that the Secretary recommends the elimination as far as possible of all special committees, the work to be done by the permanent committees. By doing this the affairs of the Society can be handled more expeditiously and smoothly.

DISTRICT MEETINGS AND CONFERENCES

It is gratifying to note that the attendance at the District Branch Meetings has continued to be large and the high standard of the scientific programs has not been lowered.

The conferences of the County Secretaries and the County Legislative Chairmen were well attended and productive of much good being well worth the slight expense entailed.

LEGISLATION

Matters of this character will be handled by the report of the Legislative Committee. The Secretary has, however, one recommendation to make. Of late a rather harmful procedure has crept into our legislative work, not through any fault of the Committee or the Executive Officer, but through the over zealous enthusiasm of some of our members who think that by rushing resolutions through the House of Delegates or pressing matters in their county societies they will hasten action, not realizing that six to eight months elapse between the annual meeting and the meeting of the State Legislature and what is a fact today is often by tomorrow a dream of the past. Your Secretary has had years

of experience in these legislative matters and he sincerely recommends that all resolutions affecting legislation should be automatically referred to the Committee on Legislation.

The Secretary expresses his thanks to Dr Peter Irving, Assistant Secretary, and Dr Joseph S Lawrence Executive Officer, for the assistance and efficient cooperation which they have extended him throughout the year.

		12,578
Elected after October 1, 1933, and dues credited to 1934		270
		12,848

It is a pleasure to be able to report that there are less delinquents than last year and one third of the Counties are Honor Counties, by far the largest number ever recorded. Allegany, Champaign, Columbia, Cortland, Essex, Fulton, Greene, Lewis, Montgomery, St Lawrence, Schoharie, Schuyler, Seneca, Sullivan, Tioga, Tompkins, Warren, Wyoming and Yates.

DANIEL S DOUGHERTY, *Secretary*

April 1, 1934

* The delinquents are paying daily. In fact over 150 have paid since writing this report making those dropped for nonpayment of dues much less than last year.

REPORT OF THE COUNCIL

To the House of Delegates
Gentlemen

The Council has the honor of presenting the Annual Report which includes those of the Executive Committee, Committee on Publication, Committee on Insurance, and Journal Management Committee.

Two regular meetings have been held, April 4, 1933, and December 14, 1933, both in New York City.

Pursuant to the provisions of the By-Laws governing the constitution of the Executive Committee the following members of the Council, nominated by the

President, were elected to serve with the Officers as the Executive Committee for the ensuing year. Thomas P Farmer, Samuel J Kopetzky, James M Flynn, Stuart B Blakely and Louis A Van Kleeck.

The appointment of Standing and Special Committees was referred to the Executive Committee.

It was decided that the 1934 House of Delegates convene at 10 00 A M instead of as formerly in the afternoon.

The President was empowered to designate representatives from the Medical So-

ciety of the State of New York to meet with representatives from the New York Academy of Medicine, Department of Hospitals and the United Hospital Fund with the view of investigating the matter of Dispensary abuse and formulating recommendations which would be equitable both to the Medical Profession and the Hospitals; the number of representatives to be determined by such agreement as the President of the New York Academy of Medicine and the President of the Medical Society of the State of New York may decide upon.

The Council placed itself on record as not approving of the fee schedule that had been promulgated in relation to operations on crippled children unless it has been approved by the House of Delegates.

The resignation of Dr. Orrin Sage Wightman as Editor-in-Chief of the JOURNAL was accepted with regret.

Dr. George R. Critchlow of Buffalo and Dr. William A. Krieger of Poughkeepsie were nominated to fill the vacancy on the Nurses' Advisory Council appointed by the Regents.

EXECUTIVE COMMITTEE

The Executive Committee has held regular meetings on the second Thursday of each month with the exception of July and August. At the first of these meetings it organized by electing Frederick H. Flaherty, Chairman, and Samuel J. Kopetzky, Vice-Chairman. At the same meeting Orrin Sage Wightman was appointed Editor-in-Chief; Frank Overton, Executive Editor; Lorenz J. Brosnan, Counsel, and Thomas H. Clearwater, Attorney.

Although the work of the Executive Committee is of necessity more or less routine, it is extremely important as there are many important problems brought to it to solve, all of which have had the most careful consideration by the Committee.

In accordance with the By-Laws the Annual Budget was prepared and referred to the Trustees for the necessary appropriation.

The renewal of the contract with the Executive Officer was approved and referred to the Trustees.

On nomination by the President the following were elected members of Standing Committees:

Scientific Work: William F. Jacobs.

Public Health and Medical Education: George W. Kosmak, Mahlon H. Atkinson,

Leo F. Schiff, Martin B. Tinker, Edward G. Whipple, Clayton W. Greene and Nellis B. Foster. Russell L. Cecil was later appointed a member of the Committee to fill the vacancy left through the death of Dr. Foster.

Legislation: John J. Buettner, Bernard B. Berkowitz, B. Wallace Hamilton and Edward E. Haley.

Arrangements: Andrew Sloan, Chairman, Edward E. Powers, Dan Mellen, George M. Fisher, Thomas H. Farrell, F. M. Miller, William Hale, Jr., Bion P. Allen and William B. Roemer.

Economics: Charles H. Goodrich, Joseph P. Garen, Frederick M. Miller, George C. Vogt, Joseph C. O'Gorman, Cassius H. Watson, Terry M. Townsend, Frederick S. Wetherell and Edward T. Wentworth.

Public Relations: William H. Ross, George M. Fisher, Oliver W. H. Mitchell, Augustus J. Hambrook, William D. Johnson and Thomas H. Cunningham.

The following Special Committees were appointed by the President:

Medical Research: John J. Morton, Jr., Chairman, John Wyckoff, G. Canby Robinson, Augustus B. Wadsworth, Edwin MacD. Stanton, Herman G. Weiskotten, Joshua E. Sweet, Allen O. Whipple, Marshall Clinton, Winfield W. Scott, Burton T. Simpson, Frank A. Hartman, Simon Flexner and Peyton Rous.

Insurance Committee: Frederic E. Sondern, Chairman, Chas. Gordon Heyd and Louis A. Van Kleeck.

Prize Essays: James Ewing, Chairman, Allen O. Whipple and Leon H. Cornwall.

Publication: Frederic E. Sondern, Chairman, Peter Irving and Louis A. Van Kleeck.

To Study the Field of Preventive Medicine: William H. Park, Chairman, Edwin MacD. Stanton, Morris Maslon, Russell G. Nelson and Alfred E. Shipley.

To Study the State Control of Certified Milk: Alec N. Thomson, Chairman, Edward J. Wynkoop, Charles Hendee Smith, Paul Brooks, Douglas P. Arnold and Walter Lester Carr.

To Prepare a History of Medicine in the State of New York: Nathan B. Van Etten, Chairman, Alvah S. Miller and William H. Ross.

To Consult with the Saratoga Springs Commission: John Wyckoff, Chairman,

George Scott Towne and L. Whittington Gorham.

Temporary Emergency Relief: James N. Vander Veer, Chairman, Hyzer W. Jones and Albert G. Swift.

James N. Vander Veer was reappointed *Liaison Officer* to act with the State Department of Health in the Control of Venereal Diseases.

To Study the Entire Question of Publication of the Journal and Report back to the Council: Arthur W. Booth, Chairman, Floyd S. Winslow, Edward E. Haley, George W. Kosmak and Peter Irving.

Sub-Committee of the Committee on Public Health and Medical Education, to Study the Question of Children in Schools for the Deaf throughout the State: Wendell C. Phillips, Chairman, Augustus J. Hambrook and Mahlon H. Atkinson.

Terry M. Townsend was appointed *Chairman* and Thomas F. Laurie, *Secretary*, of the newly created Section on Urology.

The resignation of James Ewing as Chairman of the Committee on Prize Essays was accepted and Albert C. Snell appointed to fill the vacancy.

The principles in the Report of the Governor's Committee on Workmen's Compensation were approved.

The Rules and Regulations Governing Malpractice Defense as adopted by the House of Delegates were sent to every member of the Society in accordance with instructions received.

The Secretary was empowered to inform the Orange and Dutchess-Putnam County Medical Societies that the State Society had no objection to any form of arbitration which they may desire, but that the arbitration must not be held in New York City.

It was recommended that the House of Delegates grant the Permanent Retired Members the privilege of Malpractice Defense.

Moses Keschner, Chas. Gordon Heyd and Nathan B. Van Etten were nominated to fill the vacancy on the Grievance Committee created through the expired term of Dr. Keschner on December 31, 1933.

The Committee placed itself on record as being of the opinion that the case method is by far the best way of providing medical care under the Civil Works Administration.

A letter was sent to Dr. Goldwater, Commissioner of Hospitals, expressing the ap-

preciation of the Society of his action barring from the wards of the City Hospitals all compensation cases that were not emergency ones.

The aims and purposes of the Society for the Prevention of Asphyxial Deaths were approved and the House of Delegates requested to instruct the Delegates to the American Medical Association to sponsor a similar resolution in the House of Delegates of the National Organization.

Arthur W. Booth was appointed Chairman, Chas. Gordon Heyd, Samuel J. Kopetzky, Frederic E. Sondern and James F. Rooney, members of a Committee on Trends in Medical Practice with Special Reference to Socialized Medicine and the best way of combatting it; the recommendations of the Committee to be presented to the House of Delegates, through the Report of the Council. Vide Auxiliary Report.

The following resolution was approved:

That inasmuch as the duties of the Standing Committees of the Medical Society of the State of New York cover all the ordinary and foreseen activities and interests of the Society, that the Speaker of the House of Delegates, the Executive Committee and all those in authority be asked to endeavor to eliminate in most instances the authorization of Special Committees of the House of Delegates, believing that the proper reference for new matters should be to a Standing Committee of the Society authorized by the By-Laws for such purpose.

COMMITTEE ON INSURANCE

Present-day economic conditions have probably been the cause of many unusual problems which have had the best attention of your Committee and have been duly reported to the Executive Committee.

It is noted with regret that probably for the same reason there has been an approximate 10% decrease of participants in the Group Plan. To ameliorate this condition our Indemnity Representative instituted partial payments of premium during the year and used such other means in his power to relieve the situation. In these ways he accomplished the re-establishment of the policies in 50% of the cases.

The codifying of the rules applying to indemnity insurance adopted by the last House of Delegates has been well received

and has materially simplified the administration.

THE JOURNAL

Pursuant to the resolution adopted by the House of Delegates on April 3, 1933, a Special Committee was appointed

"To study the entire question of the JOURNAL, with a viewpoint of submitting recommendations as to organization, form of JOURNAL, finance, and possible profit-making administration and report back to the Executive Committee not later than September 15, 1933."

An exhaustive study was made by a Committee under the Chairmanship of Arthur W. Booth. The other members being Floyd S. Winslow, George W. Kosmak, Peter Irving and Edward E. Haley. The Executive Committee became convinced that, while financial profit from operation is not to be expected at this time, a substantial reduction in cost of publication to the Society could certainly be effected.

To accomplish this end the Executive Committee found it necessary and wise to completely change the arrangements for publication after the appearance of the December 15, 1933, issue of Volume 33. The special office that had been maintained was discontinued. The Society then entered into contractual agreement with Mr. Thomas R. Gardiner, whereby, for a definite yearly sum, Mr. Gardiner assumed all business and financial conduct with the usual editorial assistance of publication. The terms are financially very advantageous to the Society. The duration of the contract is two years.

The agreement provides for complete control by the Society of all content, both reading matter and advertisements. For this purpose a Journal Management Committee was created consisting of Arthur J. Bedell, Chas. Gordon Heyd, Peter Irving, George W. Kosmak and Frederic E. Sondern.

This new Committee was given specific instructions for its guidance. Advertisements are to be accepted only if they conform to the Rules and Regulations of the Council on Pharmacy and Chemistry of the American Medical Association. Original articles, in order that they represent the formal scientific activities of the Society, are to be accepted, at present, from those papers which have been actually presented before the Annual Meeting, a District Branch Meeting or one of the Meetings of the sixty County Societies in the

State. Other articles of state-wide interest, such as may proceed from the State Department of Health may be considered eligible. It was felt that this policy of selection would ensure to authors who had gone to the trouble of reading their papers the priority of consideration which their effort deserves, and would avoid unnecessary delays in appearance.

Under date of April 12, 1934, the following formal report was presented to the Executive Committee by Frederic E. Sondern, Chairman of the Journal Management Committee:

"The Journal Management Committee begs to report that, beginning with the issue of January 1, 1934, it has exercised active supervision of publication in accordance with policies laid down by the Executive Committee.

"The JOURNAL has appeared in new size and new format. The editorials have been expanded. Unacceptable advertisements have been expunged. Original articles that did not fit in the category of official presentation have been rejected.

"The double task of keeping down cost and at the same time producing a journal of proper content has been in some ways embarrassing to the Committee. The early issues were not to the satisfaction of the Committee in size of type or general printing workmanship. Changes were required, and have been made as fast as was consistent with issuance of a semi-monthly JOURNAL, in the effort to bring the magazine more nearly up to the ideals of the Committee.

"Criticisms have been invited and gratefully received. They have been very helpful. Further comment will be particularly welcome. It is hoped that, before long, additions in the advertising section may provide an increase in the number of pages devoted to reading matter."

COMMITTEE ON PUBLICATION

Since the appointment of a Journal Management Committee, the sole remaining duty of your Publication Committee has been supervising the publication of the Directory. This has been done in the usual way this year at a cost of the allocated one dollar per year per member and the additional sum of \$696.74. Current conditions in advertising and sales explain the decrease in revenue.

Your Committee is of the opinion that with the improvement of business condi-

tions generally, a plan of publication can be proposed which will make the Directory cost the Society less and produce a more substantial volume.

The matter of certification of specialists by National Boards is the result of an insistent and proper demand, and your Com-

mittee believes that evidence of such certification should be attached to the names of all members thus accredited.

Respectfully submitted,

DANIEL S. DOUGHERTY, *Secretary*

April 1, 1934.

REPORT OF COMMITTEE ON SCIENTIFIC WORK

To the House of Delegates:

Gentlemen:

The interest and efficiency of the Chairmen of the various sections has made it possible for the Committee on Scientific Work to determine its policies well in advance and to offer a program of high character for the 1934 meeting at Utica.

Under the direction of Dr. Jacobs a scientific exhibit unusually well coordinated with the scientific program has been arranged. The exhibits are novel, diversified, of excellent character, many of them demonstrations of well planned research and illustrative of papers to be presented at the general sessions and section meetings.

While there is no single building in Utica which would comfortably house all the sections and all the meetings, it is extremely fortunate and most assuring to find that the Committee on Arrangements, using the two principal hotels and the Westminster Church House, are able to furnish within a radius of two city blocks ample, commodious and well-arranged meeting places for all.

The scientific program we believe to be something more than interesting and instructive. It combines a considerable number of presentations of high scientific character based on careful research offered by the original workers, and thoroughly practical discussions of diagnosis and treatment by men well known for their clinical training and experience.

For the general session Tuesday afternoon there will be a symposium on Growth and Reproduction, a review of the recent extensive research discoveries concerning the pituitary and prepituitary hormonal functions. It will be pointed out that the clinical applications must follow cautiously for it is to be expected that in advances so rapid seeming contradictions must arise needing clarification if not further study. We believe the particular strength of this symposium resides in the fact that the

essayists individually are leaders in laboratory and clinical research in their respective fields.

For the Wednesday afternoon general session the subject of Forensic Medicine is to be discussed by a group of men who are earnestly endeavoring to advance this important branch of medicine as a specialty and by an experienced criminologist and psychiatrist. The establishment of the exact cause of death and mode of death is of enormous value in the progress of medicine, and for the accumulation of statistics as a basis for health policies. An understanding of criminal personalities, the implications of criminal knowledge or intent, the detection of crime, the modes of violence in their medical relations, are subjects of vast importance to society and to the due processes of law in the apprehension and prosecution of malefactors. This symposium will bring forth much new information and novelty of procedure and approach and is to be accompanied by a scientific exhibit which is illustrative and unique.

The Medical Section has a number of eminently practical papers covering everyday medical problems such as colon function, anemia, arthritis, diagnosis, and the value of newer diagnostic methods and means of approach, coupled with two papers in the broader fields of symptomatology and interrelation of the specialties.

The Section on Surgery has for Tuesday a symposium on the treatment of certain heart conditions by total thyroidectomy from both the medical and surgical aspects, the presentation being by original workers in that field; and for Wednesday a symposium on peptic ulcer which covers the natural history, statistical review of cases, and discussion of types of treatment.

The Obstetric and Gynecology Section papers show the tendency for these specialties more and more to make use of

the fundamental facts of metabolism, bacteriology and pathology.

The Section on Neurology and Psychiatry groups papers which cover the neuropsychiatric sequelae of various traumatic and birth injuries, the practical diagnostic and therapeutic considerations of infections of the cerebrospinal tissues and coverings, the anomalies of vascular origin, the results of tumor obstructions, and the backgrounds for various vegetative disorders and psychic states.

The Section on Pediatrics shows a series of papers accompanied by carefully planned and individually executed demonstrations. There will be explanation and discussion of some of the newer methods of intravenous and forced perivascular modes of treatment, two papers involving cutaneous allergic reactions of recent discovery and three papers dealing with the problem of diseases of the new born.

The Section on Dermatology and Syphilology has a group of papers of practical character which will be rapidly presented in accordance with the methods of this specialty and thoroughly discussed. It will have as an invited guest a distinguished dermatologist and author. A number of exhibits and demonstrations have been arranged.

The Section on Ophthalmology and Otolaryngology has the innovation of an instruction hour preceding the regular session. This plan is worthy of consideration by other sections. There will be at least two scientific exhibits of original work in these specialties.

The Section on Public Health devotes itself on Tuesday to a series of practical papers upon a wide range of topics and on Wednesday to a most important symposium on Asphxia arranged by Paluel J. Flagg, M.D., President of the Society for the Prevention of Asphyxial Death. The speakers are of national renown and there will be an extensive scientific exhibit demonstrating how some fifteen thousand deaths annually in the United States might be prevented.

The new Section on Urology has the interesting and valuable arrangement of devoting one day to a symposium on the treatment of gonorrhea and the second day to one on obstructive uropathy, and the new Section on Radiology to various modes of treatment for different types of cancer on Tuesday and to newer diagnostic methods on Wednesday.

Dr. Richard Kovacs of New York has again arranged an interesting session on Physical Therapy for Wednesday morning covering the physical therapy in hospitals, in general practice and in health resorts and for industrial injuries.

We thank Dr. Charles Norris for his invaluable assistance in arranging the symposium on Forensic Medicine, and Dr. Robert T. Frank for his advice and personal efforts in the formulation of the Tuesday afternoon program.

Respectfully submitted,

WILLIAM A. GROAT, *Chairman.*

April 1, 1934

REPORT OF COMMITTEE ON LEGISLATION

To the House of Delegates:

Gentlemen:

Your Committee on Legislation is again obliged to submit its report before the close of the legislative season. However, probably before you convene the Legislature will have adjourned, in which event this report will be completed by a supplementary statement.

The Committee has been very busy this year. Conferences have been held with representatives of several organizations regarding proposed legislative matters. Particularly among these is a conference that was held with the Legislative Committee of the State Hospital Association re-

garding the drafting of a hospital lien bill.

The chairman has regularly sat in conference with the chairmen of the other standing committees when invited to do so by President Flaherty. These conferences have been held monthly and have proven of considerable value. They have afforded us an opportunity of discussing matters that committees have thought had a legislative significance.

We used the usual methods of stimulating the County Society Chairmen to make contact with their legislators and to arouse interest in prominent local individuals in proposed legislation which has a bearing upon public health regulations or the practice of medicine.

Early in the session we called together the chairmen of the County Society Legislative Committees for a conference in Albany. Twenty-five counties were represented. The Executive Officer supplied all those present with copies of bills which were then before the Legislature and we reviewed them, discussing the particular features in each proposed amendment and recording our approval or disapproval, with instructions to the Executive Officer to represent us before the appropriate legislative committees.

We have had an unusually large number of bills to care for this year. At present, of the thirty six hundred bills before the Legislature, one hundred and eighty have some relation to public health, the practice of medicine, or the activities of physicians. Among these are many with such little merit that one wonders why they were introduced. Nevertheless, we have studied them all very carefully as they have been introduced and sent copies of the important ones to the chairmen of the county committees, calling attention to the objective of the amendment and asking for comment. We have also advertised the name and number of all bills in the weekly bulletins that we have issued. These bulletins go to the chairmen of all the County Society committees and also to members of the Council and representatives of local medical organizations who have requested to be kept informed. Our bulletin service has been very helpful. On special occasions, as, for instance, when our hospital lien bill was being considered in committees, we asked through the bulletin that communications be sent to members of the committees and later, at the conferences where the Executive Officer appeared representing us, it was apparent that the members of the committees had received requests from their constituency to give the bills special consideration. In our experience, the letters written by physicians or prominent lay persons to their legislators, are more influential than debates at public hearings.

Again it is very gratifying to report that our representative, Dr. Lawrence, is being very courteously received by the members of the committees in the Legislature. He is frequently called to their conferences to explain the medical or public health aspect of bills and consulted by legislators sometimes at the request of their county chairmen.

In developing support for the hospital lien bill, we addressed a request to all of the general hospitals in the state for a statement of the amount of money they lost in either June or July of 1933 that they might not have lost had the proposed amendment been a part of the law at that time. The hospitals responded very promptly and at the same time sent copies of their letters to their legislators. The statements they sent afforded us material for a powerful argument. We are also very grateful for the direct support they gave through their communications.

At your request, we have had a bill drafted and introduced amending the Education Law so as to prevent any but physicians from giving anesthetics. The bill has been very widely opposed. Hospital organizations, individual hospitals and surgeons have written resolutions and statements of their opposition to your committee and to the introducer of the bill and the committee to which it was referred.

We also endeavored to draft a bill in accordance with your instructions proposing an amendment to the General Municipal Law. We offered the proposal to the legislators, but were unable to get anyone interested enough to take the bill, particularly because it was learned that the State Department of Social Welfare would not support the amendments.

Your committee would like to suggest that when the House of Delegates has legislation to propose, it submit the proposition to the Committee on Legislation with instructions to act in accordance with its best judgment. This suggestion is made because of the conflict which has arisen this year. We solicited and secured the hearty cooperation of the hospitals in supporting our lien bill, but aroused their opposition by our nurse anesthetist bill. It is unfortunate that two such amendments should be attempted at the same time.

We distributed, through our bulletin, comments on the report submitted by the committee appointed by the Governor to make a study of the Workmen's Compensation Law, and later sent a copy of the bill that was drafted on the basis of the report. At the time of writing this we are soliciting state wide interest in the advancement of the bill. Sufficient time has not elapsed since it was printed to ascertain what opposition it may arouse. We shall have more to say about this in our supplementary statement.

The osteopaths have introduced their bill of last year and then submitted two others, modifications of the first. All of these ask the privilege of prescribing drugs and performing certain forms of surgery. We have offered the objections that we made in previous years.

The usual antivivisection bill appeared and had its hearing. The Committee on Medical Research effectively opposed the bill.

An antivaccination bill has been introduced. We are using our influence to have it killed in committee.

The chiropractors have not as yet introduced a bill, but they have circulated briefs and proposed amendments to the law in their favor. They sought and were granted an opportunity to discuss their proposals with the Regents. To this conference the President of the Society, the Legislative Committee and the Executive Officer were invited and requested to discuss the re-

quests of the chiropractors. Since that conference we have learned that the Regents refused to support the proposed amendments.

We have had no outright state insurance bills, but certain of the objectionable occupational disease bills have recurred. Nevertheless, the bills that would affect physicians in their practice are increasing in number and are requiring more and more study and effort on the part of your committee.

We are very grateful to the chairmen of the county committees, to representatives of other organizations and to other members of our bulletin list for the aid they have rendered us in bringing our point of view to the legislators.

Respectfully submitted,

HARRY ARANOW, *Chairman*

April 1, 1934

REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

To the House of Delegates:

Gentlemen:

Your Committee on Public Health and Medical Education begs leave to submit the following report for the current year.

This report has been made brief in the hope that a large number of members of the Society will read it and discuss with their delegates the subjects which are herewith presented. The report follows the form of previous reports from this Committee. The relative position of the various subjects does not indicate their importance.

GRADUATE EDUCATION

The following table is a report of the graduate courses to be sponsored by the State Society for county medical societies under the direction of this Committee for the current year.

*Bronx County.....	Physical Therapy
Cayuga County.....	Subject not decided
Chemung County....	Neurology
Chenango County...	Internal Medicine
*Columbia County...	Dermatology & Syphilology
*Cortland County....	Clinical Conference
Cortland County....	Internal Medicine
Herkimer County...	Traumatic Surgery
Jefferson County....	Infections
*Madison County....	Heart Disease
*Monroe County....	Infections
Montgomery County.	Traumatic Surgery
*Niagara County.....	Physical Therapy

*Onondaga County...	Dermatology & Syphilology
Orange County....	Pediatrics
Otsego County.....	Traumatic Surgery
*Rockland County...	Internal Medicine
St. Lawrence County.	Infections
Schoharie County...	Traumatic Surgery
Steuben County....	Neurology
Sullivan County....	Internal Medicine
Tioga County.....	Internal Medicine
*Tompkins County...	Clinical Conference.

(Cortland County is having a course in the spring of 1934 and joined with Tompkins County for a clinical conference last fall.)

This table is necessarily incomplete at the time of the writing of this report. An asterisk before the county indicates that the course has been completed. As it is necessary to submit this report several weeks in advance of the meeting of the House of Delegates and as many of the courses will not be completed until after the time of that meeting, it is impossible to submit at this time a summary of the year's work. The Committee has continued its practice of keeping detailed records of all courses and hopes to publish later as a separate article a comparative summary for the different years.

The subject of the continual education of the physician has been thoroughly discussed in our previous reports. The need for this instruction is universally recog-

nized Furthermore, plans for offering this instruction are in effect in many state medical societies It is gratifying to report that the amount of this work in the various county societies of this State continues unabated During the present year another county has held a course for the first time since the State Society has solely sponsored this work Fifteen county medical societies which had courses last year are having courses this year Four societies, Chemung, Jefferson, St Lawrence, and Sullivan, have the distinction of having had a course each year since the responsibility of this work was assumed by the State Society This is a record of which these county societies may be very proud Several other counties have a record approaching this and have done excellent work As has been emphasized before, the real success of this work depends upon the efforts of the officers and committees of the county societies In one or two instances the co-operation which the State Committee has received from the local officers has been disappointing

A clinical conference, which was arranged for a joint session of Cortland and Tompkins counties, was most successful In its last annual report this form of instruction was discussed in detail The Committee again wishes to direct attention to the advantages of the clinical conference and hopes that more county societies will avail themselves of this plan In connection with the didactic lectures, county societies should also take advantage of the opportunity to receive practical instruction in the examination and treatment of local patients presenting difficult problems

The Committee is glad to report that some county societies are sponsoring their own programs of graduate education In addition to the work in New York and Kings counties, an excellent program has been formulated in Queens County and Monroe County has started a splendid program this year In the work sponsored by the State Committee the policy has been to make the lectures instructive and to correlate the topics so that the attention of the classes is concentrated on a more or less definite subject The Committee is endeavoring each year to make its plan more comprehensive Such progress necessarily must be slow

The Chairman of the Committee gave a report on the work in graduate education of this Society before the Annual Confer-

ence of Secretaries of Constituent State Medical Associations held in Chicago on September 22, 1933, under the auspices of the American Medical Association This report was published as an article in the December *Bulletin* of the American Medical Association The Committee is in correspondence with similar committees of other State Societies Much has been gained by the interchange of information between these similar bodies of different State Societies

GENERAL PUBLIC HEALTH ACTIVITIES

Your Committee has no further report to make regarding the maternal mortality study which was attempted by the State Department of Health two years ago No information has been sent to the Committee for review

The Committee has no further report to make regarding tuberculosis reporting The Committee is continuing to cooperate with the State Department of Health in improving this work

The Committee has aided in arranging programs dealing with cancer for several county societies

The Committee is glad to report that as a result of the joint efforts of the State Department of Education, the Public Relations Committee and this Committee there has been an increased tendency, especially in one large city, to have the medical examination of school children made by private physicians

The Committee has no particular matters to report regarding periodic health examinations or physical therapy

Through joint action between the Public Relations Committee and this Committee a sub-committee has been appointed to make a special study of the deaf and hard of hearing children of this State This sub-committee consists of Dr Wendell C Phillips, Chairman, Dr Hambrook, and Dr Atkinson It is the purpose of this sub-committee to work for the conservation of hearing of children with potential loss of hearing through early and adequate otological care and to see that children with permanent loss of hearing shall receive adequate medical and educational care This sub-committee will make its own report to the House of Delegates

The Committee has offered its services to Mr Frederick Daniels, Director of the State Temporary Emergency Relief Association and Commissioner Parran of the

State Department of Health in a study of the nutritional status among children in families on relief rolls. The Committee recommended that these studies be made under the direction of the local county medical societies.

The Committee has made a special attempt to provide postgraduate instruction on orthopedic subjects with the hope that physicians might be able to take care of many cases which are now being directed by state orthopedic service.

The Committee is studying the importance of arthritis as a public health problem. A recent survey has shown that chronic arthritis and chronic rheumatism, not including rheumatic heart disease, constitute by far the largest group of patients with chronic disease. Chronic arthritis cripples in the largest number of cases and kills in the smallest number. This ability to cripple without killing would seem to put this disease in the lead of all other chronic diseases as a preeminent social, economic and medical importance. A more definite report on this subject will be submitted later.

THE INDIVIDUAL PHYSICIAN AND PREVENTIVE MEDICINE

It is the opinion of the Committee that there is no reason why the physician should not participate to a greater extent in the actual performance of work in preventive medicine such as now forms a large part of the activity of health departments. On the other hand, there are many reasons why he should do so. Apparently the present condition of affairs exists principally because of the lack of some well-organized and definite plan. Conferences, committee deliberations, surveys and studies do not seem promising as affecting a change in the present procedure.

Preliminary to the consideration of such a plan it would seem wise to review certain facts which warrant suggesting this change. Official health work in most instances has had its inception in the work of physicians who always have and always will be interested in the welfare of the public. The success of any public health activity demands the cooperation of the medical profession which at all times has been ready to cooperate in an honest and efficient way. Unfortunately, too often cooperation has only meant the approval of the health department's plans with very little opportunity for the medical profession to par-

take in the planning or the execution of the particular activity. Lack of harmony, disagreement and dissatisfaction has followed as a natural sequence. Remarkable results which have been achieved in the reduction of disease and the prolongation of life are too well known to repeat. Too often the impression has been created, though not always intentionally, that these benefits have resulted from the work of the official and nonofficial health agencies. It has been forgotten that the general mortality rates have been considerably reduced by improvements in curative medicine. The largest reduction in preventable diseases have been due to sanitary engineering and bacterial immunization. At the present time at least 80 per cent of all illness is due to causes which require the care of the individual while less than 20 per cent is due to causes which can be controlled by governmental activity. It therefore might be inferred that individual hygiene is four times more important than community health. Mass activity has formed a notable feature of the service of official agencies. The health service in schools, industry and in war, all of which are splendid examples of such mass activity, have come to be looked upon as common-place and usual. Unfortunately, they have produced a sense of lack of responsibility in the individual. The public having received protection from outside sources knows less about obtaining medical care today than it did a generation ago when people had well-established contacts with their individual physician. Too often medical care at the present time is varied and disconnected and fails to offer the opportunity for the physician to use his position to disseminate public health education, an essential to any improvement in the field of public health. Mass activity has accomplished results in public health work but at the same time has destroyed this most valuable essential. In consideration of these facts it is therefore questionable whether the present set-up in public health work is satisfactory for further accomplishments beneficial alike to the public, the health agencies, and the physician. That this fact has been recognized by certain health departments is evidenced by the inauguration of plans which have as their prime motive an attempt to change the present trend from mass activity to individual care.

Your Committee believes that this Society can introduce a plan whereby the

physician will participate more directly in the field of preventive medicine. This plan must be efficient, and while comprehensive, yet not too elaborate. In principle it must be uniform, capable of being varied in various parts of the State, appeal to the public as adequate and economic and have the approval and support of health agencies.

Essentially such a plan would have physicians in definite areas agree to furnish the services of preventive medicine as now supplied by health departments as a distinctly separate part of their regular practice. A definite time for the performance of this work with definite fees for its service would add much to this distinction. When all physicians of a certain area agree on doing this work at the same hour it might be known as a public health hour. The work should include the various forms of immunization, all the phases of tuberculosis control work, well baby, pre-school, and school health examinations as well as prenatal care. The various phases of industrial hygiene offer opportunity for inclusion in this plan and it would seem as though such a plan offered the greatest chances for making periodic health examinations effective. It is most essential that this work be limited entirely to preventive medicine and that the physician assume no obligation or responsibility for general diagnosis or treatment as part of the plan. The plan should be inaugurated on a county basis by the county medical society which should control and direct its activities with the Committee on Public Health and Medical Education of the State Society aiding in its establishment and acting in an advisory capacity. The State Society could aid the county societies in promoting the proper publicity in the localities where the plan might be established. Postgraduate instruction covering the activities embraced in this plan could easily be provided by the Committee on Public Health and Medical Education. Uniform record forms formulated by this Committee and supplied by the State Society would make it possible to obtain correct information as to how much work the physician really does in the field of preventive medicine. The plan should be extended, in cooperation with the proper governing bodies, so as to provide these services for the indigent for which the individual physician should be compensated.

The Committee on Public Health and

Medical Education recommends that the House of Delegates urge county medical societies to carefully consider the establishment of a plan embodying the above principles.

MATERNAL MORTALITY

During the past year the report of the Study of Maternal Mortality of the New York Academy of Medicine has been published. Your Committee feels that it would be improper and out of place to make any comment on this report. On the other hand, it does feel that the medical profession should take an active part in the general program of maternal welfare. It offers the suggestion that commissions on maternal welfare be organized in each county medical society and that these local commissions assume the active leadership of all organizations in their respective communities working for the improvement of maternity care. It is the belief of your Committee that this problem belongs to the county medical society and should be directed by it. The definite activities of such a commission in improving maternity care will undoubtedly accomplish much more than any extensive surveys or studies. This plan has already been adopted by the Medical Society of New Jersey with excellent results. Such county maternal welfare commissions should be organized under the Committee on Public Health and Medical Education which will be prepared to advise these commissions in regard to their specific duties.

It is recommended that the House of Delegates authorize the appointment of a maternity welfare commission in each county society for the purpose as stated.

GENERAL COMMENT

The Committee has had two meetings this year both of which have been well attended.

The Committee is indebted to numerous physicians who have contributed their services and advice in facilitating its work. The Chairman wishes to express his appreciation to the officers of the State Society and the Chairmen of the other standing committees for their excellent cooperation.

Respectfully submitted,

THOMAS P. FARMER,

Chairman.

April 1, 1934.

REPORT OF COMMITTEE ON ECONOMICS

To the House of Delegates:

Gentlemen:

1. The study and work needed to quickly develop the economics of Medical Service with justice to all requires vast expenditure of time and funds. We have used our endowment of both in an earnest effort to accomplish the maximum possible, over the period of three years during which the Committee has served you in (majority) continuity. The first report (1932) sketched the fields of endeavor which called for study, readjustment, and reform and contained many recommendations calculated to arouse expression of thought and opinion among the membership of the State Society. Many recommendations were adopted, more were referred for further study (most desirable!) and a few were rejected. The second report concerned the development of a few projects of surpassing importance, the Workmen's Compensation Law, the Public Welfare Law, the Public Health Council, promotion of Preventive Medicine, General Municipal Law and its amendment, Veterans Administration Hospitals, the Financing of Sickness, Physicians and the Courts, and an amendment to the Lien Law to protect hospitals, nurses and physicians from exploitation in accident cases. With wise and helpful amendments the recommendations upon these matters were adopted by your House.

2. This, the third report, offers for your parliamentary review a few matters only. The year's work has been undertaken with the aim to bring to earliest possible co-operative or legislative completion certain important projects. This can only be done after prolonged conferences between representatives of various organizations and State Departments. It is clear to us that reforms in Hospital Economics can best be planned by conference and agreement between sub-committees of hospital officials and representatives of the State Society. Also improved legislation can be facilitated by conference with State Public Health and Public Welfare officials. What the State Medical Society alone recommends may take years to filter through various official political and legislative media, if ever. With united opinion of the Society and State Departments reforms may be

prompt and conclusive. Most of our year's work has proceeded upon these principles. This report, largely informative, deals with unfinished work undertaken with enthusiasm, and developed to a point where faith in the principle of cooperation seems justified.

WORKMEN'S COMPENSATION LAW

3. The House of Delegates, after amending certain sections, adopted this Committee's recommendations (1933) offering a new Medical Section to the Workmen's Compensation Law. Meanwhile the Governor appointed a Committee to revise the Medical Section of the Workmen's Compensation Law. From this latter Committee the Governor received a constructive final report which embodied basic principles formulated by your Economics Committee. A bill based upon this report has been drafted. Favorable legislative action will depend largely upon vigorous personal support by the members of our profession.

ECONOMICS OF HOSPITALIZATION

4. In regard to the re-referred matters under this caption and others in all of which this Committee was to share responsibility with other Standing Committees, progress has been made. Our sub-committees were appointed early in the year. After several meetings of the Standing Committee Chairmen with our President, the primary consideration of these subjects were assigned to sub-committees from the various Standing Committees to facilitate action. (This keeps traveling and meeting expenses at lowest possible total.) In January at the meeting of Chairmen of Standing Committees, our Committee was asked to prepare agenda for these conferences of sub-committees. These have been prepared, reviewed by our complete committee in meeting, mimeographed and were forwarded to the Standing Committee Chairmen in February. In all probability some of the conferences will have been held before the session of the House of Delegates convenes.

5. In general the Committee reaffirms its views concerning the Economics of Hospitalization, excepting those paragraphs disapproved by the Reference Committee

and the House of Delegates. Some of these have interested Hospital Directors and Superintendents and are being considered at joint conferences with the Committee of the State Hospital Association reported in paragraph 6 of this report.

6. Interest in the Evans and Crawford Bills of 1933 and in the State Medical Society's approval thereof led the then President of the State Hospital Association to request informal conference with representatives of our Committee. Here it was agreed that if the representatives of hospital administration and of organized medicine could meet, discuss and agree upon a solution of any of the problems of mutual interest, it would be possible to put corrective measures into effect without delay or the necessity of action by the legislature. Or, should the latter be necessary, that having established agreement, we could jointly support it at Albany. The first informal meeting occurred in July. In November an officially appointed group met our Committee. The following topics were discussed:

Definition of indigency—in relation to medical care

Principle. The indigent is the ward of the community

Indigent should pay no fees

Beds for free hospital care—reserved for indigents

Hospital rates adjusted to eliminate deficits

No corporate practice of medicine by hospitals

Hospital insurance to cover hospital service not medical care

Sub committees were appointed to study the economics of hospital relationship to the practice of

Anesthesia
Pathology
Roentgenology
Physical Therapy
House Obstetrics, and other unit fee schemes

The sub committees are actively engaged with their respective problems. As soon as they are ready to report, another joint conference will be called. The State Medical Society and the State Hospital Association will make final disposition of these matters when sub committee and joint committee actions are reported to them. Sub-committees have met and report progress. Joint Committee action may be expected in May or June.

7. In the meantime local units and groups have taken up consideration of the

problems in the Economics of Hospitalization. We appreciate that there is constantly a local complexion to such problems. However, the fundamental principles are essentially the same over the State. In Monroe County (including Rochester) a plan of clinic admission control is reported to be working effectively. Erie County has a plan of control. In the Metropolitan area representatives and hospital administrations are conferring on the problem of clinic control and related topics. General agreement has been reached that patients seeking free medical clinic care shall be required to make a financial statement. Some hospitals have put this into effect without waiting for a general official adoption. One institution reports a 10 per cent drop in clinic attendance for the first month. Bronx County investigated one thousand consecutive admissions and demonstrated that only about 48 per cent were justly entitled to free care. Westchester County calculated the value of free care for one year. Based on moderate fees and prorated to the staff members it indicated that each one had donated the equivalent of \$400 to the care of hospital patients. In Ontario County the Society contracted with the authorities for a fixed sum to do all county cases. After two years this has been abandoned and they now insist upon a return to a fee for service plan. Suffolk County continues its outstanding position in the solution of the care of the poor.

In other states experiments are in progress. Notable work has been done in Philadelphia. The outstanding principle of their activity is that no institution shall share in a fee for a service which only a duly licensed physician can render. In St. Louis a *sworn statement* of finances has been required of all patients soliciting free medical care with a result that free care cases have dropped about 60 per cent. In Battle Creek, an organization of dentists and physicians, membership open to all licensees, contracted to care for the poor of that city for \$12,000 and the administration costs of the plan amounted to \$1600 for the disbursement of the first \$6000—an example of the costs of lay administration.

The details of all these and a considerable number of others are being accumulated and analyzed by your Committee. Out of the experiences of these *trial and error* experiments should come the under-

standing of principles upon which a planned medical care may be established. It would seem to be the function of this Committee to make contact with and correlate these various activities.

PUBLIC HEALTH

8. General practitioners of medicine should be the chief guardians of the public health, and no town, city, state or federal program can be complete and efficient without participation of all licensed physicians and utilization of facilities established and made available by them. Outstanding results are on record where this has been recognized.

9. *Medical Care of the Indigent.*—We are striving toward the day when provision for the indigent shall be complete and efficient. These persons and families, while indigent, should pay no fees. They should be wards of the community as represented by organized government in village, town, city, county, state or Nation (in order of responsibility). Although indigent they should be accorded the same *free choice* of physicians as other citizens possess. It is the duty and the privilege of all physicians to share in the care of the indigent. The cooperation of the County Medical Society with governmental officers in providing medical service for the indigent is very necessary. This function includes regulation of conduct and of remuneration.

10. The financial obligations of the community recognizing these principles (para. 9) are considerable, but could largely be met by abolishing extravagance in hospitalization and free care of solvent persons. Competent medical care at home is often less costly than hospitalization. Care in private general hospitals in large cities (notably in the Metropolitan area) could be secured at less cost than is obtained in the conduct of City Hospitals. Germane to this proposition is the urgent need of extending the operation of the Public Welfare Law of the State to the Greater City of New York. In accordance with our recommendation of 1933 (approved by House of Delegates) the elimination of the Home Rule Law welfare provisions of the City Charter is imperative. This would make many embarrassed private hospitals more nearly solvent and relieve physicians

of an unjust burden of charity which should be carried by the community. Moreover, it would render unnecessary any additional hospital accommodations in City Hospitals. The desirability of State Society action aiming to accomplish this needed reform in the new Charter of New York City has been urgently presented to the Executive Committee.

11. The persons and families just above indigency (perhaps from 10 to 25 per cent of the population) present a problem of special importance. Competent, complete medical service should be available to them. They have means to live comfortably in periods of good health. Illness either shatters their financial structure or they fear it will. Two features contribute largely to their distress:

1. Hesitation and delay in consulting a physician early in illness or seemingly small ills.
2. Inflexible charges of a minority but very definite percentage of physicians.

The solution of this problem is not easy. Among physicians we can popularize the universal practice of special interest and consideration for this group. We can frequently and persistently urge this group to consult their physician early. Reasonable charges should be repeatedly assured to them. We believe that the enthusiastic promotion of periodic health examinations at restricted prices would be particularly useful to this group.

12. Early in the year it was recognized that if the principles presented in pars. 8, 9 and 10 were to be brought to fruition in any considerable degree general cooperation of our Society, State governmental departments, and welfare agencies must be obtained. It was also in our records that there was a lack of harmony in the various laws which contain provisions for the care of the indigent. At a conference of State Society officials, State Department Commissioners and charity directors, and members of our committee, the following procedure was planned:

- (a) The physical assembly of operative laws having to do with the care of the indigent excluding those dealing with custodial care. (State Commissioner Adie of the Social Welfare Department is providing a research worker for this work.)
- (b) The assembling of these into an interleaved pamphlet by our Committee, this pamphlet to be distributed to the officers of this Society, to the officers of State

Departments and the charitable organizations for opinion, comment and suggestion as to elimination of faults and introduction of improvements to the end that all laws concerning the care of the indigent shall read identically and to provide efficiently against misunderstandings, maladministration, and abuses. Moreover, it is our hope that in this way the principles presented in pars. 8, 9 and 10 can become a part of all of these laws.

- (c) All suggestions are then to be formally considered by the officials of State Departments, Welfare organizations and State Medical Society officials and agreement upon needed new legislation secured.
- (d) We have the assurances of Commissioners Parran and Adie that when the work is complete, means will be found to publish, in manual form, a single volume which will contain all of the regulations as a guide for the information of those who are charged with the administration and of those who render medical care to the poor.

While this is undertaking a long and very responsible task, we believe that ultimately an admirable service to the people and justice to the physicians of the State will result. Much of the material is already in hand. We hope to have the first copy of the pamphlet edited and in circulation before July 1st. Progress onward to the completed printed edition will depend upon the receipt of returned comments.

13. *The Medical Care Needs of the Indigent.*—On the one hand, your Committee is aware of a growing volume of complaint that our profession cannot further carry the burden of *free medical care* and of the increasing exploitation of the traditional charitable practices of our profession. There is a demand for some reasonable compensation for the service which the physician renders for the general good of the community and the exercise of a more strict control of the dole of free care. On the other hand, not a few fear that compensation for the care of the poor will be only a first step to socialization of medicine with its inevitable breakdown of standards. Potent efforts to shape public opinion to some program of planned medical care for the poor and near-poor are obvious and pertinent to the economics of medicine. The State through the agency of local authority is assuming a larger responsibility in individualized service; while other influences would lead us into the pitfalls of some scheme of *compulsory health insurance*.

Volunteer agencies offering free clinic and bed care to the sick are generally in financial distress. The way out of this complex situation is not evident. Your committee has undertaken to collect and put informational matter in proper order. No definite recommendation is possible from the data now in hand.

14. *Medicine in Industry.*—Our sub-committee has submitted an adequate report of its survey during the year which has been offered for publication in the *STATE JOURNAL*. This report shows that Medicine in Industry has been obliged to submit to the general economic situation. However, management continues to increase its interest in the health of the worker. Although receiving salary reductions the physician's recently improved position has been maintained and his financial returns are on a scale comparable to those paid in other departments.

15. *Practice of Medicine by Corporations.*—(a) Our sub-committee has reviewed varying situations in this State and elsewhere. Their report is elaborate and most interesting and has been presented for publication in the *STATE JOURNAL*. Hitherto undiscussed points are raised in this report and a clearer understanding of the actual facts may be had by studying this article when published.

(b) The Counsel of the Society, Mr. Brosnan, has written a valuable opinion on the subject of the practice of medicine by corporations. This will be published in the *STATE JOURNAL* at an early date.

16. *Financing Sickness.*—We have, in accord with instructions, continued this study. We are encouraged to believe that when the banking industry has become less apprehensive of the general economic conditions, some plan of discount facilities will be arranged for handling large credits of medical care. This is the crux of the problem. Many collection agencies and discount companies continue their practice of frauds.

We have specifications of *standards* and a provisional program for the control of these affairs. The establishment of a list of *accepted firms* entails certain costs of administration. When the money to cover

the expense is provided, we shall put our plans into effect.

17. *The Cost Analysis of Medical Practice*.—No detailed or extended work (urgently needed) has been undertaken this year because it has been deemed wise to avoid the necessary expenditure at this time.

18. This committee assisted the 140 A. M. A. *Approved Roentgenologists* of the Metropolitan area in the complete organization of its group.

The New York Society of A. M. A. *Approved Roentgenologists* is now committed to the economic problems of this specialty practice, to encourage higher standards of conduct and to combat those tendencies which may demoralize such standards.

The by-laws of this organization prescribe:

"The acceptance of membership automatically waives any and all rights to claim based on any disciplinary procedure on the part of the Society or its officers, for libel and/or slander against any or all members of the Society.," indicating that this Society is set up for the purpose of self-discipline.

19. *Radio*.—There is no censorship exercised over the *advertising programs*. The public is receiving a vast amount of misinformation. Self-diagnosis and self-treatment are encouraged and health habits and regulations of questionable virtue are being promulgated. The public-health aspect of this belongs to another committee. The economic implications are fundamental and considerable.

This Committee has proposed to the Executive Committee a program of action "on the air" to oppose the influences of charlatans and patent medicine vendors. The stories of the development and growth of the science of medicine, including recent and current events of importance, told in dramatized incidents, dialogues and short lectures would result in a better informed and more sympathetic public. Such a campaign would contribute largely to public education and indirectly prove of measurable needed benefit to practitioners. Our

proposal is receiving careful conservative consideration by the Executive Committee.

20. Acknowledgment is hereby made of the regular receipt of the following publications and communications, by the Economics Committee.

1. Bulletins from Legislative Committee, Medical Society of the State of New York, relative to bills being submitted in Albany.
2. Bulletin of Medical Society of County of Nassau.
3. Westchester County Medical Bulletin, Westchester County Medical Society. Monthly Bulletin.
4. Health News, Department of Health, Weekly Bulletins.
5. Social Welfare Bulletin, Department of Social Welfare, Albany, N. Y. Monthly Bulletin.
6. Detroit Medical News, Wayne County Medical Society, New York State Weekly Bulletins.
7. Calhoun County Medical Society Bulletin, Battle Creek, Michigan. Occasional Weekly Bulletin.
8. Minutes of the Commission on Medical Economics, Philadelphia County Medical Society, Philadelphia, Pa.
9. Illinois Medical Journal.

21. To each of the component county societies of the State Society all minutes of our Committee's meetings have been forwarded. Minutes were supplemented by a series of bulletins. We have exchanged minutes with the Economic Committees of other State and County organizations. The Committee now has equipment to render such communications in a more acceptable form in so far as mechanical composition is concerned.

Respectfully submitted:

FREDERIC E. ELLIOTT, *Chairman*
CHARLES H. GOODRICH, *Secretary*

April 1, 1934.

REPORT OF COMMITTEE ON ARRANGEMENTS

To the House of Delegates:

Gentlemen:

Your Committee on Arrangements announces the following arrangements for the Meeting of the Medical Society of the State of New York to be held on Monday, Tuesday and Wednesday, May 14, 15, and 16, in Utica, New York.

Arrangements have been completed with Hotel Utica, Hotel Martin and Westminster Church House in providing rooms for the Scientific Sessions and Technical and Scientific Exhibits.

The first meeting of the House of Delegates will be called to order at 10:00 A.M., Monday, May fourteenth. All meetings of the House will be at Hotel Utica. An address of welcome will be given by Mayor Samuel Sloan of the City of Utica. The dinner for the House of Delegates will be held at Hotel Utica on Monday evening. This event promises to be most enjoyable as the Committee on Arrangements has planned some novel features.

The Scientific Sessions have been divided between the two hotels and Westminster Church House, the latter being within two blocks of the hotels. The sections on Medicine, Dermatology and Syphilology, Gynecology and Obstetrics, Ophthalmology and Otolaryngology, Neurology and Psychiatry, Pediatrics, Urology, and Radiology will be held at Westminster Church House on Tuesday and Wednesday mornings. The Section on Surgery will be held in the ball-room at Hotel Martin on Tuesday and Wednesday mornings. Public Health, Hygiene and Sanitation, and Physical Therapy at Hotel Utica. The General Sessions will be held in the ball-room at Hotel Martin on Tuesday and Wednesday afternoons. The registration for Delegates will be held at Hotel Utica

and general registration for members at Hotel Martin. Printed programs of the different Section Meetings will be provided at the registration desks for Delegates and members. Scientific Exhibits of unusual interest as well as the Technical Exhibits have been assigned space in Hotel Martin.

On Tuesday evening at Hotel Utica the Annual Banquet Meeting of the Medical Society of the State of New York will be held under the presidency of Dr. Frederick H. Flaherty. It is expected that Dean Lewis, M.D., President of the American Medical Association will be the guest of the State Society at this Meeting. Following the banquet, transportation will be provided for those in attendance to the Players' Theatre, where the Players Club of Utica, N. Y., one of the most successful amateur dramatic organizations in America, will present the well-known play, "The Late Christopher Bean." The cast will include many local physicians, whose talents as entertainers need little introduction to the medical profession of the State.

The Committee for the entertainment of the ladies promises the ladies in attendance a most delightful and enjoyable time.

The Committee on Arrangements desires the profession to make early reservations for banquet tickets, which are expected, this year, to be in demand. Seats will be reserved in the order in which applications are received. It is respectfully suggested that the physicians send their reservations by mail to Dr. William Hale, Jr., 264 Genesee St., Utica, N. Y. Tickets may also be purchased during the Meetings of the Sections at the registration desks. The tickets, including both the dinner and entertainment are two dollars (\$2).

Respectfully submitted,

ANDREW SLOAN, *Chairman*

April 1, 1934

REPORT OF THE PUBLIC RELATIONS COMMITTEE

To the House of Delegates:

Gentlemen:

The personnel of the Public Relations Committee has remained the same as of the preceding year, viz.: William H. Ross, Brentwood, Secretary; George M. Fisher,

Utica, William D. Johnson, Batavia, Oliver W. H. Mitchell, Syracuse, Augustus J. Hambrook, Troy, Thomas H. Cunningham, Glens Falls, and James E. Sadlier, Chairman, Poughkeepsie. Such a committee, many of whom are past officers of the State Society, all of them men interested

in the activities of their state and county organizations, has been most valuable in developing necessary activities and in establishing contacts with other organizations working in the field of medicine, and in lending encouragement to county medical societies to become active in their relationships which have to do with advancing present-day medical affairs.

All members of the committee have given generously of their time and assumed the various duties assigned to them. Seldom do we ever find an absentee at our committee meetings.

The reports of the sub-committees are prompt and indicate thorough painstaking services rendered in the tasks allotted to them. Meetings of the State Committee have occurred monthly with the exception of August and November when it was considered expedient to conserve the financial resources of the committee.

The chairman of this committee has met monthly with President Flaherty and the chairmen of the other standing committees, to discuss the activities of the various committees and disentangle the many interlocking conditions which develop and which should be allocated to some one particular committee. Formerly there was a considerable amount of lost effort and unnecessary expense attendant upon a lack of proper differentiation between the activities of some of the committees. This has been eliminated by the thoughtful action of your President in calling for a monthly conference of the chairmen, with him as the presiding officer.

All activities of the Public Relations Committee of this Society have more or less bearing on the field of the committees of Public Health and Medical Education, Medical Economics, and Legislation. In fact, it might be considered that in many instances the Public Relations Committee is the one to prepare the way and arrange a portion, at least, of the cooperation required by the other committees. This is especially so in Public Health and Medical Economics, hence it can be readily seen that these monthly conferences are most valuable.

The Committee has constantly before it the necessity of forming contacts with the governmental and lay organizations and frequently meets representatives of such organizations in conference, smoothing out difficulties that have developed, and en-

deavoring to adjust them to meet present-day medical standards.

It is gratifying to report that, to date, all such conferences have resulted in a better understanding of the particular subject considered. The agencies conferred with have been most grateful for assistance rendered by your committee.

Conference with the Department of Correction resulted in full-time physicians being disallowed to do outside medical practice to the detriment of local physicians of a community.

Conference with the Department of Health has developed a more satisfactory understanding with regards to fees for the treatment of crippled children as well as an improved distribution of these cases to the surgeons of the state.

DEAF AND HARD OF HEARING

Conferences with the New York League for the Hard of Hearing have resulted in a joint sub-committee of this committee and the Committee on Public Health and Medical Education being arranged, which sub-committee will work with the New York League for the Hard of Hearing, and endeavor to lead and direct their efforts. This subject is a new field and the need for study and strenuous work is very evident.

The Sub-committee on the Deaf and Hard of Hearing plans to make a study of the deaf and hard of hearing children in the state; both in the state institutions for the care of the deaf and in the public schools. The committee organized at a meeting held in New York City, October 10, 1933, as follows: Wendell C. Phillips, M.D., of New York City, Chairman, Augustus J. Hambrook, M.D., representing the Public Relations Committee, and Mahlon H. Atkinson, M.D., representing the Committee on Public Health and Medical Education. Miss Estelle E. Samuelson, of the New York League for Hard of Hearing was selected secretary. The committee is concerned principally with two problems—the care of the deaf in state institutions and the care of the hard of hearing children in the schools of the state. The medical care of the deaf children (those born without or having lost most of their hearing before speech had been established), and second, the medical care of the children with potential hearing impairments and hard of hearing children (those who have lost all or part of their

hearing after speech had been established).

There are three day and seven residential schools for the deaf in the State of New York containing about 1,700 children. Approximately 150 children are committed to these institutions annually. It is a common practice to admit children to these schools without a suitable otological examination, and in most cases no otologists are on the staffs. Several of the State institutions have been visited by members of the committee. It would seem that every school for the deaf in the State should be required to have, either a permanent otologist or visiting otologist on its staff, and that the otological care of these children be more directly supervised by the Bureau of Special Schools. The committee has compiled a list of otologists in the State of New York, such list to be available for appointments to State institutions and for the examination of the hard of hearing children in the public schools of the State.

In the public schools of the State of New York, it is established that from 4 to 10 per cent of the children, show some degree of hearing defects, that only cursory examinations are made by either the school physician or the nurse as to hearing defects, that proper otological examinations are difficult to obtain because of the expense involved, and money is not available to pay for such examinations. Deafness has been excluded as a condition to be treated under the Crippled Children Law. A few cities of the State have special classes for the hard of hearing children, but far too little is being done in this respect. New York City, Schenectady, Syracuse, Albany and Gloversville are showing the way in their efforts to give special attention to the children with hearing defects.

The Medical Society of the State of New York can render valuable help to the State Education Department in this all important study. Some means must be devised to make available a thorough otological examination of all children found with hearing defects, so that they may receive proper instruction by teachers specially trained for this important work.

The State of New York pays \$600 per year for each child in the schools for the Deaf and Hard of Hearing, besides thousands of dollars appropriated each year for new work etc. Can the benefit of the children, is one of the questions this

sub-committee will endeavor to bring to your attention, when the full report is made at some future date.

We are fortunate in having as Chairman of this joint sub-committee Dr. Wendell C. Phillips, who is most thoroughly informed as to the condition existing throughout the State with reference to the Deaf and Hard of Hearing.

REGIONAL CONFERENCES

Again this year we are holding regional meetings in different sections of the State and hearing from the chairmen of the Public Relations Committees of the several county medical societies invited to attend each conference. At these meetings the aims and purposes of the State Committee are outlined. Advice as to handling local medical questions is given, and the State Committee, in turn, learns at first hand just what is being done in each county with reference to the Public Relations of Medicine.

This is the second year that we have conducted these Regional Conferences and we believe them to be of decided advantage in educating the physicians composing our county units along the lines laid down by your State Committee on Public Relations.

The ultimate success of the State Committee's efforts depends upon the activity of the individual County Society committees. Your committee has conferred with the State representatives of organizations whose programs relate them to public health or the practice of medicine, with more or less satisfactory results in having programs modified or so constructed as to give the practicing physicians a greater opportunity for cooperation. But we have not always been able to secure as effective cooperation from our County Committees as we should have in order to accomplish the best results. One reason for this is that your committee does not always have as much information as it should have regarding the activities of these various agencies in the different counties. We have asked the County Societies to make surveys of the public health activities in their respective counties. A number have complied with our request and some very excellent surveys have been submitted. Unfortunately, no uniform method of preparing a survey has been developed and so the reports are not exactly comparable. In those counties where the investigations have been thorough and the committees

making the investigations have been retained, very definite progress has been made in public relations; in fact, the advantages those counties have gained over others have so impressed your committee that we have come to the conclusion that one of the most important activities which the State Society could encourage immediately is to help every County Society make a thorough investigation, recording the number of agencies whose programs, with budgets, relate to the practice of medicine or public health. Your committee is fully persuaded that all investigations should be made according to a definite plan which will permit of a comparison and evaluation.

We have observed with what ease and accuracy the organizations with which we have worked were able to present data upon problems under discussion collected state-wide; while we were obliged to base our discussion upon very limited information and in many instances impressions gathered by some of us in our visits to County Medical Societies. The uncertain character of our information has many times led us to accept data collected by some one of the lay or governmental agencies. This has not always been the best policy for us, because, naturally, the agency that collects the information does so from its own point of view and to establish its own program. No agency can be expected to have the point of view of the practicing physician uppermost all the while, and, therefore, we are satisfied that the State Society owes it to itself to provide a way of investigating the activities of its various units, collecting and studying the data in a comparative way and basing its future program upon the findings of such a general survey. *We recommend* that the collection of data should be supervised by our Executive Officer, but he will need assistance. Therefore, we suggest that a physician be employed as field agent whose prime duty shall be to aid County Society Public Relations Committees in making the surveys suggested above and later assist the Societies themselves in developing programs that will make the greatest use of the information collected by the surveys. It is most important at this time when schemes for socializing medicine are likely to originate anywhere in the State and from any organization, that our organization has at its command the most accurate data regarding its activities and

the activities of its component societies and individual members. We cannot afford to rely on information supplied by those who would socialize us.

MEDICAL ASPECTS OF THE PUBLIC WELFARE LAW

The present administration of the medical aspects of the Public Welfare Law is far from satisfactory and your committee believes that this should be adjusted through conference with local governmental officials and the Public Relations Committee of each County Medical Society. At present, in a few counties, the relationship with welfare officials, and the fees for work done in caring for the indigent, are satisfactory, but in most of the counties the medical men are either receiving nothing for their services or they are demanding more than should be required for the care of indigents. Hence this committee issued the following bulletin under sanction of the Executive Committee:

COMPENSATION OF PHYSICIANS FOR SERVICES RENDERED INDIGENTS

Physicians are not concerned with the care of indigents for the purpose of gain but to render needed services in the prevention and treatment of disease. Compensation sufficient to protect physicians against economic loss is rightfully expected and should be provided from public funds.

The Public Relations Committee doubts the wisdom of adopting a fee schedule—in itself—as a guide for compensating physicians for the care of indigents. The committee is of the opinion that a committee in each county society should establish close cooperative relationship with government representatives. In conference they should decide the compensation to be paid physicians.

It is to be especially stressed that compensation for the care of indigents will be minimum and not representative of charges made by physicians for like services rendered patients supporting themselves from personal funds.

Cooperation between government welfare officials and duly elected representatives, preferably the Public Relations Committee, of the County Medical Society, should result in a satisfactory agreement.

LECTURE TO MEDICAL STUDENTS

Upon invitation from the Deans of each of the nine medical schools of the State it

was arranged for our secretary, Dr William H Ross, to deliver, in each medical school, to the senior students, a lecture dealing with Organized Medicine and Medical Public Relations. It has been most heartening to the committee to note the response from the Medical Schools and their evident appreciation of the fact that the Medical Society of the State is interesting itself in the future of the coming medical man. I believe this is one of our most important activities for it is beginning with the young man before he is graduated and encourages him to become a real factor in the County and State Medical Society.

STATE-AIDED COUNTY HOSPITALS

Your committee has watched with interest and concern the administration of the state-aided hospitals in the counties of Wyoming, Lewis and Greene and has assisted your President in adjusting a radical difference of opinion in the management of the Lewis County Hospital. Impending trouble between the Medical Board and the Board of Managers of the Greene County Hospital was easily cared for through the active cooperation and assistance of the Commissioner of Health and your Public Relations Committee.

It gives me pleasure to suggest that the State Commissioner of Health has been most cooperative in his desire to see to it that the physicians working in each one of these hospitals shall have adequate opportunity to carry on their particular type of professional work, and is observing most rigorously "The Rules and Regulations Governing State aided County Hospitals," which were approved by the Medical Society of the State of New York, the Commissioner of Health of the State of New York, the Public Relations Committee of the Medical Society of the State of New York during the year 1929, and which are as follows:

Rules and Regulations Governing State aided Hospitals

1 All registered physicians residing in the county shall be eligible to membership on the staff. Physicians residing outside of the county may use the hospital but cannot become voting members of the staff.

2 From their number they shall nominate for election by the board of managers a medical board of not less than five members.

3 The medical board, subject to the approval of the board of managers, and the State Commissioner of Health shall have supervision and control of all medical service in the hospital. This shall include appointments for the necessary,

efficient and adequate surgical, medical, special and nursing services of the hospital, the preparation of rules and regulations for the conduct of the professional work of the hospital and the formulation of whatever by laws seem necessary for the efficient conduct of its (medical board's) business.

Your committee believes that the above rules and regulations although few in number, are sufficient and that it is not necessary to develop any further rules and regulations as provided for by the House of Delegates, April, 1933.

It is respectfully requested that observance of these rules and regulations governing state-aided hospitals shall be left in the future with the Committee on Public Relations. There should not be a dual responsibility in this important matter.

The House of Delegates at the annual meeting in 1933 referred to the Public Relations Committee the following question:

"Why so few physicians form part of the organization or are employed by the National Health Organizations?"

This is one of the two problems submitted wholly to the Committee on Public Relations by the last House of Delegates and has been given thought and study by this committee with the following conclusions:

Physicians frequently are not interested in National Health Organizations because of being so busy with their private practices along the lines of curative medicine.

National Health Organizations are mostly concerned with preventive medicine. The average physician does not feel at home in that field of medicine. He received his training long before the importance of preventive medicine was understood and before much teaching of it was done. Even now not enough time is devoted to it in our colleges.

The physician still regards himself as an emergency man and is interested only in well developed pathology. Since it is difficult to interest him in preventive measures among his own private patients we cannot expect to interest him in preventive medicine on a national scale.

The type individual he is, the kind of training he has had, a lifetime of working only with the sick, all affect his attitude toward Public Health Organizations.

Many physicians have been alienated from Public Health Organizations by their frequent determination to ignore the medical profession and to infringe upon terri-

tory rightfully belonging to it. Their lack of understanding of the need of a satisfactory economic basis for medicine—all of these enter into the physicians' lack of interest.

That there should be a closer cooperation no one will deny. Such cooperation must come about through educating the public, the National Health Organizations and the medical profession. This eventually will result in cooperative effort which will bring about the betterment we all are working for and eventually mean a greater proportion of professional personnel in the National Health Organization.

REFERENCE FROM THE HOUSE OF DELEGATES, APRIL, 1933

The House of Delegates of the Medical Society of the State of New York at its last annual meeting in April, 1933, referred to the Committee on Public Relations for study and plan of action, the following subject, viz:

"To develop a plan to prevent the State Department of Health from becoming an agency for the treatment of crippled children."

This reference from the House of Delegates was given to a subcommittee, who has given it careful consideration from every angle and your committee believes that little or nothing can be done about this matter except by repeated conferences with the State Department of Health and the development of a program acceptable both to the Commissioner of Health and the medical profession of the state.

Such conferences have been held from time to time for the past several years and have uniformly resulted in a more satisfactory understanding of the situation and have been of material advantage to the surgeons of the state doing orthopedic work, as well as to the public at large, and the children who come under the jurisdiction of the Crippled Childrens Act.

REFERENCE FROM THE HOUSE OF DELEGATES, APRIL, 1933

"In conjunction with the Committees on Public Health and Medical Education and Medical Economics to draft a desirable Public Welfare Law."

This committee has appointed a subcommittee to consider with the Committee on Public Health and Medical Economics this reference from the House of De-

legates, but the sub-committees have not been able to confer sufficiently to render a report at the present time and respectfully request that an additional amount of time be allotted them before opening up this subject of medical care of the indigent in this period of social reconstruction and uncertain conditions. A supplementary report will be presented when the study is completed.

REFERENCE FROM THE HOUSE OF DELEGATES, APRIL, 1933

"In conjunction with the committees on Public Health and Medical Economics and the Counsel of the State Society, to study the organization of the Public Health Council and Regulations of the Sanitary Code."

This, likewise, has had an insufficient amount of time for proper study and development of a plan.

It is suggested that an additional amount of time be given the above named three committees in order to consider this most important reference.

FUTURE WORK OF THE COMMITTEE

Make competent surveys of the work of the medical profession in each county of the state.

Stimulate and endeavor to activate county medical societies in developing the Public Relations of Medicine.

Efforts to stimulate the individual members of the profession into greater activity with reference to the Public Relations of Medicine.

Instruct the Medical Profession as to what is being done by lay organizations, and show them that one of the reasons why medicine may become socialized, and about the only reason, is because of medicine's unwillingness to work with other agencies who are trying to direct the trends of medical service. The sooner we take the first step, which is a completed survey in each County Medical Society, in directing the forces now trying to change the form of medical practice, the better it will be for the future of our profession.

Greater effort to get the young doctors interested in their Medical Relations to the public and in their county society activities.

The work next year should be done in each county society. It is there that the problems must be solved.

The work of this committee has been

enhanced through the intimate and very cordial cooperation and interest in the Public Relations of Medicine shown by our President Dr. Frederick H. Flaherty, and the Chairman of the Committee on Public Health and Medical Education, Dr. Thomas P. Farmer. We wish to express to them our very sincere thanks and appreciation.

Our Executive Officer, Dr. Joseph S. Lawrence, has been most intense in his desire to further the work and activities of your committee and has worked diligently during the past year to enlarge the scope and assist the committee in developing proper medical Public Relations throughout the state.

Your committee has earnestly endeavored to develop an active interest in the Public Relations of Medicine throughout the state. It feels encouraged by the active

way in which many of the county societies are taking hold of the various problems of present-day medicine; but it recognizes that there still is a vast amount of work to be done; that up to date it might be said that only the surface of the great problem has been handled.

If medicine in this state is going to escape socialization there must be a united profession in each county activating itself in the interests of a better and broader Medical Public Relations, and assuming a leadership over all organizations having to do with the health problem. Therefore, we bespeak your very careful consideration of all of the problems relating to the activities of this committee.

Respectfully submitted,

JAMES E. SADLIER, *Chairman*

April 1, 1934

REPORT OF THE COMMITTEE ON MEDICAL RESEARCH

To the House of Delegates:

Gentlemen:

In behalf of your Committee on Medical Research, I have the honor to present the following report:

The many upsets in the elections last fall made it certain that there would be a different alignment of the committees appointed with the opening of the Legislature. As soon as the personnel of the Committees could be determined, an effort was made to inform all members of the Code Committee in regard to the attitude of the State Society toward animal experimentation. This work was actively carried on by personal letters from influential members of the community and by letters from members of the committee. All County Medical Societies in the state were contacted in regard to the essential differences between the Humane Societies and the Antivivisectionists.

Mr. Breen introduced a bill into the Assembly, identical with the perennial Vaughn bill. At the hearing on this bill on February 28, the following distinguished members of the medical profession presented arguments against the bill: Drs. Peyton Rous, Florence Sabin, and C. P. Rhoads of the Rockefeller Institute; James W. Jobling, Professor of Pathology at

Columbia University; John Wyckoff, Dean of New York University and Bellevue Hospital Medical College; G. Canby Robinson, Dean of Cornell Medical School; George Whipple, Dean of the University of Rochester Medical School; Frederic Sondern, representing the Academy of Medicine, New York City; Augustus Wadsworth, representing the State Laboratories; Walter L. Mattick, of the State Institute for the Study of Malignant Disease and Buffalo Medical School; Barbara B. Stimson, Assistant Surgeon at the Presbyterian Hospital, New York City, and Harold Rypins of the State Department of Education.

Dr. Murphy, who is now an Assemblyman, and who annually appears for the opposition was present and spoke for the bill. Several members of the Antivivisection Society also appeared to speak in favor of the bill. No convincing reasons for the amendment were brought forward by those favoring the bill.

Your Chairman wishes to thank Dr. Joseph S. Lawrence, Dr. Frederic Sondern, and Dr. Peyton Rous for their valuable assistance during his term of office.

Respectfully submitted,

JOHN J. MORTON, *Chairman*

FREDERIC E. SONDERN, *Treasurer.*

REPORT OF THE BOARD OF TRUSTEES

To the House of Delegates:

Gentlemen:

Throughout the year the Board of Trustees carefully studied every budgetary item presented by the Executive Committee, reduced every possible expenditure to necessary limits, and continued a careful scrutiny of every financial proposal with the purpose of conserving every resource for the future needs of the Society.

The Treasurer's report shows extraordinary strength in a depression year, and such a superior quality of investment, largely due to the acumen of Dr. Sondern, that every member may justly congratulate himself upon the financial position of his organization.

The elimination of the usual deficit from the Journal account is a gratifying saving at a time when organized medicine is being sharply attacked by lay organiza-

tions which are trying to dominate the distribution of medical service.

The need was never greater for strong financial support of defensive and offensive plans for the promotion of the best interests of the medical profession.

The time has come when every member must realize the importance not only of maintaining strong reserves but also the necessity of arming the Society for a battle which threatens the very life of medicine as a profession which desires to render the highest quality of service to all who need it.

Imminent emergency may require increased financial support from every member of the Society and strong cohesive action.

NATHAN B. VAN ETEN, *Chairman*

April 1, 1934

REPORT OF THE BOARD OF CENSORS

To the House of Delegates:

Gentlemen:

The Board of Censors convened in the Offices of the State Society, 2 East 103rd Street, New York City, December 14, 1933, at 4:00 P. M. to hear the Appeal of Dr. Edward E. Hicks from the action of the Medical Society of the County of Kings with respect to the levying of the assessments for the year 1933.

The following Censors were present: C. Knight Deyo, Louis A. Van Kleeck, Clark G. Rossman, Raymond G. Perkins, Edward R. Evans, Stuart B. Blakely, James M. Flynn, Henry W. Ingham—Frederick H. Flaherty, President presiding—Daniel S. Dougherty, Secretary. The Legal Counsel of the State Society was also present.

After a careful consideration of the facts presented, the Appeal was denied on the following grounds:

First: Each County Medical Society is given the right to fix the amount of the annual dues and assessments to be collected from its members; (Membership Corporation Law)

Second: Each County Society shall have full power and authority to enforce discipline among its members and obedience to its rules, and to expel or otherwise discipline its members as it may deem for the best interests of the Society; (Membership Corporation Law)

Third: In accordance with its by-laws, the respondent Society fixed at its Annual Meeting the dues and assessments for its members for the year 1933;

Fourth: The By-laws under which these dues and assessments were levied by the respondent Society upon its members, were duly approved by the Council of the Medical Society of the State of New York;

Fifth: The appellant, Dr. Hicks, has failed and refused to pay the dues and assessments duly levied by the respondent Society as aforesaid.

Respectfully submitted,

DANIEL S. DOUGHERTY, *Secretary*

April 1, 1934.

REPORT OF THE COUNSEL

To the House of Delegates
Gentlemen.

Your Counsel herewith submits his report for the activities of the Legal Department of the Medical Society of the State of New York for the period from February 1, 1933, to and including February 28, 1934. It will be noted that this report covers a period of thirteen months.

This has been a busy year indeed both in court and in consultation. Within the proper confines of a report of this character conclusions only can be stated, but these give no fair picture of the amount of work involved or the responsibility assumed by our Department.

At the outset of this report, your Counsel wishes to acknowledge his indebtedness for the assistance, cooperation and many acts of personal kindness on the part of officers and committee men of your Society.

In making his report your Counsel adheres to the convenient category employed in previous years whereby his activities have been divided into three main divisions: (a) The actual handling of malpractice actions before courts and juries and in the appellate tribunals, (b) counsel work with officers, Committees and individual members of the Society and (c) legislative advice and activities.

LITIGATION

The possibility of a malpractice action and the hazard to the physician in having his rights passed upon by twelve lay jurors has been so often written and spoken about by your Counsel that it is unnecessary in this report to comment at any great length upon this subject.

Your Counsel is pleased to be able to report that in the field of litigation his

TABLE I

Comparison of the Number of Suits Instituted and Disposed of in 1932-1933 and 1933-1934

	Instituted		Disposed of

Pending on February 28, 1934	594			

associate, Mr. William F. Martin, has continued his splendid work. From individual members of the Society whom he has defended and from many Supreme Court judges throughout the State have come to me expressions of approval of Mr. Martin's ability and splendid personal qualities. Excellent work has also been done by your Counsel's associate, Mr. Thomas H. Clearwater, the attorney for the Society. Mention should also be made of the splendid spirit of loyalty and devotion shown by your Counsel's entire office staff.

In connection with the accompanying Table I it should be noted that this year we have treated as one case actions where a wife is the main plaintiff but her husband also sues for loss of services, or where a child is the main plaintiff and there is an accompanying action by the father for loss of services. These really constitute but one case and are tried as such, and hence we have followed this method in our present report.

For the purpose of proper comparison, therefore, we have omitted the loss of services actions from last year's table.

With this preliminary statement, we note that there were commenced in the present thirteen-months reporting period 230 actions, as against 225 during the previous eleven-months reporting period. We disposed of 204 actions as against 158 actions during the preceding reporting period. These figures, of course, do not include a large number of claims in which we were successful in persuading the claimants or their attorneys not to bring suit. There remain a number of claims outstanding in which suit may ultimately be brought. Of the 204 actions disposed of during the reporting period, 41 have been settled. In 160 actions we have obtained judgments for the defendant after trial, or they have been disposed of through dismissal, discontinuance or abatement. In 3 cases only was judgment rendered in favor of the plaintiff.

We were also successful in securing favorable results from the Appellate Division in 5 cases which were appealed.

It will be noted from Table I that there were pending 594 cases.

Following is a list of the subject of litigation proper to point out that your

First: Each of us offered to your members given the right to adequately protect themselves from the annual dues and the hazard of litigation selected from its rank of your group plan. (Corporation Law) a decade it has won

the commendation of the members of your Society. Mention here should be made of the splendid work done by the Insurance Committee under the able leadership of Dr. Frederic E. Sondern. This Committee representing your Society holds a number of meetings every year in connection with the problems that are before them for consideration.

Table II hereto appended, gives a comparison of the number of members insured in 1931, 1932, 1933 and 1934, and the number of members in the County Societies, and the percentage of insured members in the County Societies, and in the entire State Society. The figures are sufficiently clear to obviate the necessity of extended comment.

COUNSEL WORK

During the period of this report, your Counsel has prepared for publication in the Society's Journal articles in the nature of editorial comment. These editorials have included the following:

- Insanity as a Defense in Criminal Cases.
- Illegal Practice of Medicine by a Licensed Physiotherapist.
- Private Hospitals—Control over Unruly Patients.
- Physicians—Good-will of Practice not Subject to Taxation at Death.
- Property Rights in Gifts Given in Contemplation of Marriage.
- The Medical Grievance Committee Decides an Important Case.
- Hospitals—Conditions Attached to Testamentary Gift Held Valid.
- Jurors—Misconduct Held Contempt of Court.
- The Vasko Case.
- Hospitals—Power to Discipline Physicians on its Staff.
- Malpractice—Foreign Body—Physicians Held Blameless.
- Malpractice—Recent New York Decision Exonerating Physician.
- Criminal Law—Statute Providing for Alternate Juror.
- Pharmacists—Liability for Negligence in Filling Prescription.
- Insurance—Surgeon's Policy Against Illness and Accidental Injury.
- Malpractice—Foreign Body.
- Physician and Patient—Privileged Communications.
- Federal Court Ruling on Chiropractic.
- Medical Testimony—Legal Rights of Unborn Child.
- Personal Injury Action—Liability of Golf Player.
- Validity of Contracts to Provide Professional Services during Lifetime.
- An Ungrateful Patient.
- Legal Practice of Medicine—Diagnoses Held Violation of Statute.
- Contracts—Agreements between Physicians Limiting Practice.

Your Counsel has also digested and there have been published in the State Journal reports upon malpractice actions which it has been felt were of special interest to the members of the profession. The case reports published during the previous year are as follows:

Claimed Negligent Herniotomy.
Alleged Negligent Operation of the Right Eye.
Death Due to Status Lymphaticus.
Treatment of Injuries to Hand Sustained in an Accident.
Particle of Steel in Eye.
Burn from Lamp Treatment.
Claimed Negligent Diagnosis and Treatment of Right Leg and Shoulder.
Claimed Negligent Delivery.
Alleged Negligent Treatment of Fractured Fibula and Internal Malleolus.
Alleged Malpractice in Diagnostic Work.
Claimed Negligent Treatment of Syphilis.
Ambulant Treatment of Hernia.
Fracture of Pelvis Claimed to Have Resulted from Delivery.
Burn Discovered Subsequent to Operation.
Alleged Improper Treatment of Fracture.
Alleged Injury to Tooth during Tonsillectomy.
Broken Aspirating Needle.
Claimed Incorrect Diagnosis of Mastoiditis.
Claimed Failure to Diagnose Pelvic Condition.
Death Following Hysterectomy.
Claimed Negligence to Infant after Delivery.
Subglenoid Dislocation of Humerus.
Malpractice Cause of Action Barred by the Statute of Limitations.
Burn from Electrical Knife.
Claimed Negligent Application of Argyrol to Throat.
Epileptic Seizure during Treatment.
Portions of Placenta Retained after Delivery.
Charges of Negligence in Performing Hysterectomy.
Alleged Negligence in Performing Plastic Operation.
Broken Needle Embedded in Jaw.
Erroneous Diagnosis of Tumor.
Gauze Sponge Swallowed by Child.
Alleged Negligent Treatment of Laceration of Palm.
Broken Aspirating Needle.
Alleged Negligent Administration of Diathermy Treatment (2).
Glaucoma Following Treatment of Eyes.
Burn Following Use of Cautery Knife.
Alleged Negligence in Plastic Surgery.
Alleged Negligent Operation for Hemorrhoid.
Claimed Negligence in Operation on Eye-socket.

Your Counsel is pleased to learn from the members of your Society that they find these reports and editorials interesting and instructive.

In addition to his other duties, your Counsel receives frequent requests for opinions on various subjects. It should be remembered that the Executive Committee of your Society has ruled that requests for legal opinion, whether coming

from individual members of your Society or from component County Societies, must in the first instance be referred to that body for action. If the Executive Committee deems the inquiry a proper one for opinion by the Legal Counsel, it refers the same back to him for reply. Some of the matters upon which advice has been thus rendered are the following:

Communication requesting information in regard to hospital records: "As to the legal and moral grounds on which any doctor or interne on a hospital staff, might have access for purposes of study and research to the medical records of the patients of the hospital, including the private and semi-private patients of other doctors."

Inquiry as to whether it is ethical for a doctor to practice his profession under a contract, and do anything he sees fit and still continue to be a member in good standing in a County Medical Society.

Inquiry from a physician as to the advisability of obtaining a signed release from patients before operation.

Communication from a physician concerning the legality of a surgeon extracting teeth in the course of his work in oral surgery.

Communication from a physician as to whether or not it is proper for an optometrist to be permitted to be installed in a County Hospital for the purpose of doing refraction and filling his own prescriptions for glasses, this being done under the supervision of an oculist.

Communication from a physician requesting information concerning the Welfare Laws: (1) Are physicians required to make known diagnoses? (2) Are physicians required to list to welfare officers all treatments?

Inquiry as to whether or not the New York State sales tax affects physicians.

Inquiry from a component County Society asking for some concrete suggestions with respect to ridding the community of chiropractors.

Inquiry from a component County Society regarding a proposal to incorporate as a membership corporation.

Communication from a physician requesting an interpretation of the State Nursing Law.

Inquiry as to the correct method of reporting unethical nurses to the proper authorities.

Inquiry as to whether or not a charity patient receiving attention in a hospital can sue for malpractice the physician in charge of his case, said physician receiving no compensation from the hospital or from the patient for services rendered.

Communication inquiring as to the rights of a physician, where a patient has died, and where there is a will contest, including specific inquiries as to the following: (1) Are the doctor's records private and privileged communications? (2) Is it proper for any lawyer or group of lawyers to invade a physician's office and obtain access to records therein? (3) To what extent may the doctor testify in court under such circumstances.

Communications requesting an opinion as to whether the administration of anesthesia by a nurse anesthetist constitutes a violation of the Medical Practice Act.

Communication requesting a form of consent

to operation to be obtained by a physician (1) Where the patient is over age, (2) where the patient is an infant

Inquiry from a physician on behalf of a hospital staff with regard to the existing laws and regulations concerning donors for blood transfusions, with especial regard to procedure in an emergency case

Inquiry from the Secretary of Medical Board of a hospital regarding hospital records, including the following specific inquiries (1) What is the right of the Courts to subpoena records? (2) What are the rights of the Court or Judge to hold in Court or impound hospital records until the completion of a trial

Inquiry as to the civil and criminal liability of a physician arising out of an operation for the sterilization of a patient

Inquiry from the secretary of a component County Society requesting advice on the following matters (1) In the absence of the employment by contract or otherwise of a physician or physicians, and a surgeon or surgeons and other specialists to care for all welfare cases arising in the city, has the city or its Welfare Department the legal right to select, designate and publish a specific list of physicians, surgeons and other specialists to do the Medical Welfare work arising within the city, thereby discriminating against other physicians who are equally capable? (2) Is there any provision in the Public Welfare Law, or any ruling to the effect, by means of which the patient may choose the physician whom he wishes to care for him?

Inquiry as to the legal responsibility of a doctor for the acts of an anesthetist in the following cases (1) In cases where a physician anesthetist is used, (2) in cases where a nurse anesthetist is used

Communication requesting the following information and opinion (1) Legal definition of the practice of medicine, laws pertaining to use of X ray apparatus to make radiographs of human bodies, to the reading or interpreting of such films and to the treatment of patients by X rays (2) Is an interpretation of an X ray film of the human body a special privilege reserved for physicians only? (3) What decisions in law have been rendered pertaining to uses of X ray apparatus, interpretations, diagnosis and treatment?

Communication from a County Society requesting an opinion regarding the deduction for income tax purposes of the money received from the school district by a duly appointed Medical Examiner

Communication from a physician as to coverage under group policy for acts of assistant

Inquiry as to advisability of enforcing collection of bill for professional services where malpractice suit is threatened

In addition to the foregoing your Counsel has been asked to render advice and consider the following

Communications requesting citation of cases discussed in editorials appearing in the New York State Journal of Medicine

Communications requesting information as to when the Statute of Limitations runs in a malpractice action where the patient is a minor

Communication requesting a form of consent

to operation to be obtained by a hospital to cover the following cases

Ward Cases

- | | |
|--------------|---|
| 1 For adults | In general operative work
In mutilating operations |
| 2 For minors | In general operative work
In mutilating operations |

Private Cases

- | | |
|--------------|---|
| 1 For adults | In general operative work
In mutilating operations |
| 2 For minors | In general operative work
In mutilating operations |

Inquiry as to whether or not an examiner in lunacy who is sued for malpractice, is covered by the group policy

Communication from physician requesting further information as to a ruling in the Surrogate's Court dealing with the question of when, in legal contemplation a child is considered as living. Said ruling having been the basis of an editorial in the New York State Journal of Medicine

Inquiry from a physician seeking information as to the availability of published reports of medicolegal cases

Communication requesting legal authorities on the question that arises where a doctor sues for his fee on an implied contract

Inquiry from a physician requesting the provisions of the Civil Practice Act covering the question of Confidential Communications

Opinion rendered to the Executive Committee in the matter of a protest by a doctor against the assessment levied by a County Medical Society upon its members for the current year and his contention that this assessment should be the subject of review by the Medical Society of the State of New York

Appearance as Counsel to the Board of Censors of the Medical Society of the State of New York in connection with an appeal taken by a member of one of the component County Societies

Your Counsel has been in conference and consultation with members of the Journal Management Committee and also prepared the existing contracts entered into at the time of the change of management of the STATE JOURNAL

Your Counsel has also rendered his assistance to this Committee in the matter of the applicability of the New York State Sales Tax to the New York State Journal of Medicine, and to other matters which have come before them for review

Your Counsel has also examined the proposed revised Constitution and By Laws of a number of County Societies and has rendered advice and made suggestions in connection therewith

Your Counsel has also advised and consulted with the Medical Economics Committee of the State Society from time to time with respect to various matters under its consideration

Your Counsel acted as one of the Counsel to the Joint Committee of the

State Society and the Academy of Medicine in connection with the proposed changes of the Workmen's Compensation Law. This Committee held a large number of hearings and your Counsel advised and conferred not only with the Committee but with various sub-committees and from time to time prepared various amendments and gave legal advice on the matters that came before the Committee for action.

Your Counsel has also advised from time to time with the Chairmen or members of other Committees of the State Society.

LEGISLATIVE ADVICE AND ACTIVITIES

Your Counsel's opinion has been requested and has been promptly given with respect to a number of proposed bills that

have come before the Legislature affecting the Medical Profession.

He has also drafted or assisted in the drafting of a number of bills to be introduced at this session of the Legislature.

CONCLUSION

We cannot close this report without expressing our thanks to the many members of your Society who have aided us in the defense of malpractice actions. Without this assistance so generously given, we could not have obtained the results shown by this report.

Respectfully submitted,

LORENZ J. BROSNAN, *Counsel*.

February 28, 1934

REPORT OF THE FIRST DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

A meeting of the Executive Committee composed of the Presidents of the counties of the Branch was held at the Vassar Alumnae House, Poughkeepsie, on May 19, 1933. At this meeting an invitation from the Westchester County Medical Society was accepted to hold the Annual Meeting at the Grasslands Hospital, Valhalla.

The program to be on Cardiac Arrhythmias and Collapse Therapy in Tuberculosis, together with an Operative Clinic and Case Demonstration in Chest Surgery.

In accordance with this invitation the Annual Meeting was held at Grasslands Hospital on October 11, 1933, with an attendance of one hundred and ninety-one and the following scientific program was presented:

Address of Welcome, Andrew A. Eggeston, M.D., President, Medical Society of the County of Westchester.

"Cardiac Arrhythmias," James F. Rooney, M.D. Discussed by Milton J. Raisbeck, M.D.

"The Use of Quinidine Sulphate in Cardiac Arrhythmias," Frederic C. Conway, M.D. Discussed by Frederick W. Holcomb, M.D.

"Operative Clinics and Case Demonstrations in Chest Surgery," George C. Adie, M.D., Director Surgery, Grasslands Hospital.

"Motion Pictures Illustrating Normal and Abnormal Cardiac Mechanism and Electrocardiograph," Lewis M. Hurxthal, M.D.

"Pulmonary Tuberculosis," Howard Lilienthal, M.D.

"Tuberculosis Cases Under Collapse Therapy," J. Burns Amberson, M.D. Discussed by the members of the staff of Grasslands Hospital.

"State Society Problems," were discussed by Frederick H. Flaherty, M.D., President, and Daniel S. Dougherty, M.D., Secretary of the Medical Society of the State of New York, Orrin S. Wightman, M.D., Editor of the NEW YORK STATE JOURNAL OF MEDICINE.

I wish to take this opportunity to thank the members of the First District for their attendance. Also the officers and members of the Westchester County Society, together with Dr. Claude W. Munger and his staff at Grasslands Hospital, Drs. Rooney, Conway, Raisbeck, Holcomb, Hurxthal, Lilienthal and Amberson, together with Dr. Joseph S. Lawrence, Executive Officer, State Society and Mr. James Bryan, Executive Secretary, Westchester County Society for their participation and cooperation in making this annual meeting a success.

Respectfully submitted,

C. KNIGHT DEYO, *President*.

April 1, 1934

REPORT OF THE THIRD DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The Third District Branch, which includes the Counties of Albany, Columbia, Greene, Rensselaer, Schoharie, Sullivan and Ulster—a rural district—submits for your consideration some features of unusual interest to your official body and the medical profession of the State at large:

Albany County Medical Society, with the interested cooperation of the municipal officials of the City of Albany, have been carrying on an intensive program of instruction and information of both the medical profession and the laity in an endeavor to return to the family physician the supervision and administration of those health measures related to vaccinations, immunizations, pre-school physical examinations and the T. B. testing of school children of early high school age.

At Catskill in Greene County there was opened last August a County Hospital. It was made possible by financial assistance from the State Department of Health. The Hospital was quickly filled to capacity and has been functioning smoothly and efficiently. The staff is composed of all licensed physicians within the County. The consulting staff is composed of physicians of eminence within easy access. Through the cooperation of the State Department of Health, the Medical Board obtained the right to select its own officers.

Columbia County is one of the few in this State which has established a County Health Department, abolishing all town and city health officers. The board of managers is appointed by the Supervisors of the County. A working majority of the board of managers is composed of physicians who are chosen from a list submitted to the Supervisors by the County Medical Society.

The County Health Department has been functioning efficiently since March, 1933, actively supervising the health and sanitation of the county water supplies, dairies, milk distribution and school health matters, among its many duties.

It has been acceptably received by the medical profession and laity of the County.

A few minor points of friction have arisen, usually of ethics, which the board of managers has quickly corrected.

The State Department of Health has not influenced the appointment of the personnel, nor has it been otherwise meddlesome but has been helpful in giving advice and guidance when sought.

Some of the County Societies in the Third District Branch have availed themselves of one or more of the postgraduate courses offered by the Committee on Public Health and Medical Education of the Medical Society of the State of New York. These courses have been enthusiastically received. Attendance, in some instances, has not been what would seem to have been merited, probably due to the hour of meeting not having been well chosen for the particular county or time of year. These rural counties are hopeful that this activity of the State Society will be continued.

In one instance at least—a county society which, in response to the request of the Governor of the State, submitted in good faith to the board of supervisors, a list of nominations for commissionerships under the Alcoholic Beverage Control Law—regrets that such a list had been submitted. It would seem that this is a questionable function to be exercised by a County Medical Society.

Our rural district is deeply concerned and trust that they will not be deprived of supervised and restricted administration of anesthetics by qualified nurses. Also that some method may be arrived at to lessen the very large economic loss to institutions, the medical and nursing professions which is incurred by the irresponsible injured—largely the result of automobile accidents which are so prevalent in rural areas.

Respectfully submitted,

CLARK G. ROSSMAN, *President.*

April 1, 1934

REPORT OF FOURTH DISTRICT

To the House of Delegates:

Gentlemen:

The Annual Meeting of the Fourth District Branch was held at Malone, Sept. 19

and 20, 1933. Although more than one-half of our members in the Branch live over two hundred miles from Malone, about one hundred and twenty attended the

meetings. Several guests were present from nearby Canadian towns and also from Vermont and Massachusetts.

The Scientific Program on the afternoon of the 19th included:

"Fractures and Dislocations of the Elbow," by Dr. Philip W. Wilson of Boston.

"What the State of New York Plans to Do at Saratoga Springs," by Dr. Carl R. Comstock of Saratoga Springs.

"The Diagnosis and Management of Goiter," by Dr. Frank H. Lahey of Boston.

In the evening, members of the branch were guests of Franklin County Medical Society at dinner at Hotel Flanagan. The rest of the evening was given up to a discussion of economic problems. The speaker of the evening was Dr. John Wykoff, Dean of Bellevue Medical College, New York City and his topic "Some Thoughts on the Present Day Evolution of Medicine." He pointed out with very keen insight the great changes that are now taking place in the practice of medicine, the reasons for the change, and probable future developments. He was followed by Dr. Robert S. Macdonald of Plattsburg on "Why the County Should Compensate Physicians for the Care of County Cases," and by Dr. Edward J. Callahan who told us "How Saratoga County Medical Welfare Work Is Handled." Our State President Dr. Frederick H. Flaherty of Syracuse very ably summed up some of our Economic Problems and told us what the State Society is doing with them.

The morning session on the 20th was unusual in that the attendance was even

larger than that of the previous afternoon. A paper on his specialty by Dr. Gavin Miller, Demonstrator in Diseases of Rectum and Colon at McGill Medical School, was enthusiastically received. Dr. William Mallia of Schenectady presented a motion picture "The Management of Persistent Occiput Posterior in Labor." The session closed with a most practical and helpful paper on "The Diagnosis of Brain Tumors from the General Practitioner's Standpoint," by Dr. Wilder G. Penfield, Professor of Surgery of McGill Medical School in Montreal.

There has been much discussion among the County Societies during the past year about the indigent county cases and several of our Counties have agreements with the *County Welfare Officers whereby the profession is paid for its services.*

At the September Meeting an Economic Committee for the Branch was appointed, consisting of the County Presidents, the County Economic Chairmen and another representative surgeon or medical man from each county society.

This Committee met in Elizabethtown in October and prepared a schedule of fees which seemed fair to both County and the professions. It is hoped that this schedule will be adopted in the Counties of the Branch thus eliminating constant friction within the county between the Profession and the Welfare Officers and eliminating the sending of county cases from one county to an adjoining county where the schedule of fees is lower.

Respectfully submitted,

R. G. PERKINS, *President*

April 1, 1934

REPORT OF THE FIFTH DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The chief activity of the Fifth District Branch during the past year was its twenty-seventh annual meeting at Oswego in the high school auditorium. There were one hundred and ten members present at the meeting, representing the Counties of Herkimer, Jefferson, Lewis, Madison, Oneida, Onondaga and Oswego. The scientific program was as follows:

"The Treatment of Hernia by the Use of Fascia; and More Especially Human

Preserved Fascia," Harry W. Vickers, M.D., Little Falls.

"The Results of Biliary Tract Surgery," Allen O. Whipple, M.D., Professor of Surgery, Columbia University.

"The Management of Uterine Bleeding," Thomas P. Farmer, M.D., Syracuse.

"Present-day Conceptions of Puerperal Sepsis," Benjamin P. Watson, M.D., Professor of Obstetrics and Gynecology, Columbia University.

"Facts Concerning the Temporary Emergency Relief Administration," James N. Vander Veer, M.D., Albany.

Each of these papers was followed by interesting discussions by various men and each paper was declared to be of distinct value to the members in their various lines of practice. In addition to this program, Dr. F. H. Flaherty, President of the Medical Society of the State of New York, spoke and emphasized problems now before the doctors of the State, discussing especially the medical relief plans in this State.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education of the State Society, discussed some of the public health problems with which the physicians of New York have to

deal, and described the graduate courses conducted by the State Society.

At the election of officers, the following men were elected:

President: William A. Groat, Syracuse.
First Vice-President: LeRoy F. Hollis, Lacona.

Second Vice-President: M. M. Gardner, Watertown.

Secretary: Fred C. Sabin, Little Falls.
Treasurer: Hermann G. Germer, Canastota.

Respectfully submitted,

EDWARD R. EVANS, *President.*

April 1, 1934.

REPORT OF THE SIXTH DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

Nothing unusual has happened in the history of the Sixth District Branch during the past year. A report of the annual meeting held in Norwich on October 18, 1933, has already appeared in the JOURNAL. The October date was about three weeks later than this District's meetings have been held in the past. Comment in general was favorable to the change. The Counties have held their meetings regularly. In the field of economics this District has not been in so bad a situation as many others have

been reported to have been. Many of us think, however, that the social and economic aspects of medical practice are undergoing permanent change, very doubtfully for the better.

It has been a pleasure and a privilege to serve the District for two years. To the signer of this report has come doubts during his time of office of the real value of District Branch organization in the State Society.

Respectfully submitted,

STUART B. BLAKELY, *President.*

April 1, 1934

REPORT OF THE SEVENTH DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The Twenty-Seventh Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York, was held on Thursday, September 21, 1933, in the College Auditorium on the River Campus of the University of Rochester. The registered attendance was 251.

The morning session was opened at 10:30 o'clock by the President, Dr. James M. Flynn, who introduced Hon. Charles Owen, Comptroller of the City of Rochester. Mr. Owen welcomed the physicians and referred to the aid which they render in prolonging the years of usefulness of those long experienced in the practical affairs of business and civic life.

The following officers were elected at the business session: President, Alfred K. Bates, Auburn; First Vice-President, Thomas W. Maloney, Geneva; Second

Vice-President, Alfred W. Armstrong, Canandaigua; Secretary, H. S. Brasted, Hornell; Treasurer, E. T. Wentworth, Rochester.

A noon luncheon was served in the students' dining hall of the University.

The State Institute for Malignant Disease sponsored an exhibit of photographs and x-ray films illustrating its cancer research.

Dr. F. H. Flaherty, President of the Medical Society of the State of New York, gave a brief address urging the officers of the County Medical Societies to confer with their county welfare officials in order to reach agreements in regard to supplying medical service to the poor and those who cannot otherwise obtain it. Securing these agreements is of extreme importance to every County Society.

Five scientific addresses were listed, all of deep interest and great practical value.

Dr. Royd R. Sayers, Chief of the Industrial Hygiene and Sanitation of the United States Public Health Service, discussed the subject of silicosis, and the deleterious effects of silica dusts compared with the effects of other dusts. The specific effects of silica are the results of its solubility. Carbon, for example, is insoluble, and is therefore not toxic, although it may blacken the lungs with its deposits. But silica is slightly soluble, and has toxic properties in addition to the irritation of its mechanical presence in the tissues. Silica produces a characteristic fibrosis, and predisposes to tuberculosis.

Dr. Charles Gordon Heyd gave a talk, illustrated with lantern slides, on the subject: "The Mechanism and Clinical Interpretation of Jaundice." Dr. Heyd reviewed the source of the bile salts in the blood and the several mechanisms by which they are retained or deposited in the tissues. The practical application of his address was a plea that doctors should bear in mind the physiology of jaundice and the various conditions that bring it about, such as vomiting leading to alkalosis, and diarrhea leading to acidosis—contrasting conditions which respond to appropriate treatment.

Dr. Byrl R. Kirklin, of the Mayo Clinic, Rochester, Minnesota, gave an address on "The Diagnosis of Pulmonary Tuberculosis," with special reference to the peculiar field of the x-ray.

Dr. Arthur J. Bedell, of Albany, gave a talk on "Medical Ophthalmoscopy, the Connecting Link Between the Physician and the Specialist." Dr. Bedell showed photographs of the fundus of the eye in various diseases, using three stereopticons loaned by the Bausch and Lomb Company, and throwing three pictures on the screen simultaneously, in order to show contrasting conditions. He showed how the eye fundus may reveal conditions in their early

stages while they are remediable. His talk was an argument for the use of the ophthalmoscope in two conditions:

1. In visual defects which are of rapid onset, often revealing kidney disease, lead poisoning, syphilis, or other serious condition.

2. In these same systematic conditions often revealing an eye disease in an early stage.

Dr. Fred H. Albee, of New York, spoke on "The Bacteriophage in Wound Treatment," tracing the history of the greater developments in the treatment of chronic infections of wounds through three stages:

1. The Carrell-Dakin method of irrigation used in the World War.

2. The Orr method, or packing the wound in gauze impregnated with vaseline and leaving the material intact for days or weeks.

3. The application of bacteriophages to the wound.

The first method depended on the constant application of an antiseptic to the wound and bacteria. The probable explanation of the second method was that long presence of the packing in the wound permitted bacteriophages to grow in the wound.

Bacteriophages were first discovered in 1915, and about fifty varieties are known, each specific for a single kind of germ. Doctor Albee's method of using them is to fill a wound cavity with a soft mixture of paraffin and vaselin, and to introduce the bacteriophages into the wound daily through a catheter.

A time schedule was followed, and every speaker began and ended on time.

Respectfully submitted,

JAMES M. FLYNN, *President.*

April 1, 1934.

REPORT OF THE EIGHTH DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The twenty-eighth annual meeting was held on Thursday, October 5, 1933, at the Cataract House, Niagara Falls, N. Y. Due to the deaths of Dr. Raymond B. Morris, President, and Dr. Frederick J. Schnell, Vice-President, the meeting was called to order by Dr. H. Wolcott Ingham, of Jamestown, the second Vice-President.

A resolution commending President Franklin D. Roosevelt for the address which he made to the convention of the American Legion October 2, 1933, and pledging the support of the physicians in each community to aid him by continuing to care for those who require medical treatment and are unable to pay for it, was adopted.

At the luncheon hour Dr. Frederick H. Flaherty, President of the Medical Society

of the State of New York, and Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education, emphasized the need that county medical societies enter into agreements with County Welfare officers in regard to supplying medical services to the poor.

The following officers were elected:

President: Dr. Richard Sherwood, Niagara Falls.

First Vice-President: Dr. H. Wolcott Ingham, Jamestown.

Second Vice-President: Dr. Herbert Smith, Buffalo.

Secretary: Dr. Henry W. Spofford, Batavia.

Treasurer: Dr. Fitch H. Van Orsdale, Belmont.

A scientific program was carried out as follows:

"Timely Economic Issues," Charles H. Goodrich, M.D., Brooklyn.

"A study of Diabetic Deaths from Autopsies," Ivan Hekimian, M.D., Buffalo, and Samuel A. Vogel, M.D., Buffalo. Discussion opened by Byron D. Bowen, M.D., Buffalo.

"What Every Doctor and Dentist Should Know about Cancer," Joseph C. Bloodgood, M.D., Baltimore, Md.

"Advances in Cancer Research, in relation to enzymes in cancer and research in the mechanism of radiation effects," Ellice McDonald, M.D., Philadelphia, Pa.

The Eighth District Branch had a very difficult year due to the death of Dr. Raymond B. Morris of Olean, N. Y., our worthy President who died September 16, 1933, after a long-continued illness. We also had the misfortune to lose another very good man, Dr. Frederick J. Schnell of North Tonawanda who was First Vice-President of our district. He died May 5, 1933. Resolutions were adopted in the honor of these deceased officers.

The Eighth District Branch is composed of eight county societies in the extreme western end of the State, whose membership is as follows:

Allegany	34
Cattaraugus	47
Chautauqua	87
Erie	786
Genesee	27
Niagara	102
Orleans	22
Wyoming	33
	<hr/> 1,088

Respectfully submitted,

H. W. INGHAM, *Acting President.*

Medical Society of the State of New York

HOUSE OF DELEGATES

The regular Annual Meeting of the House of Delegates of the Medical Society of the State of New York will be held on Monday morning, May 14, 1934, at 10:00 A.M., Daylight Saving Time, in the Ball Room of the Hotel Utica, Utica.

SAMUEL J. KOPETZKY, *Speaker*,
DANIEL S. DOUGHERTY, *Secretary*.

ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York will be held on Tuesday, May 15, 1934, at 7:00 P.M., in the Ball Room of the Hotel Utica, Utica.

FREDERICK H. FLAHERTY, *President*,
DANIEL S. DOUGHERTY, *Secretary*.

REGISTRATION

For Members

Registration for members will be held at the Hotel Martin on Monday, Tuesday and Wednesday, May 14, 15, and 16, 9:00 A.M. to 6:00 P.M.

For Delegates

Registration for members of the House of Delegates will be held in the Hotel Utica, Monday morning, May 14th, from 9:00 A.M.

TECHNICAL EXHIBITS

The Technical Exhibits will be located in the Hotel Martin, and will be open on Monday, Tuesday, and Wednesday.

VALIDATION OF RAILROAD TICKETS

Members holding railroad certificates entitling them to a reduction in return railroad fare must have same signed and

validated at the Society's Registration Desk before purchasing tickets for the return trip at the reduced fare.

128TH ANNUAL MEETING

Calling the Society to order by the President, Frederick H. Flaherty, M.D.

Address of Welcome by the Chairman of the Committee on Arrangements, Andrew Sloan, M.D.

Reading of the Minutes of the 127th Annual Meeting by the Secretary, Daniel S. Dougherty, M.D.

Address of Welcome by Samuel Sloan, Mayor of the City of Utica.

President's Address, Frederick H. Flaherty, M.D.

ANNUAL BANQUET

The Annual Banquet will be held in the Hotel Utica, Tuesday, May 15, 1934, at 7:00 P.M.

Introduction of the President-Elect, Arthur J. Bedell, M.D.

Address: Dean Lewis, M.D., President of the American Medical Association.

Entertainment: "The Late Christopher Bean," presented by The Players Club, Utica, at the Players Theater.

Tickets for the banquet including the entertainment will be \$2.00, and members are requested to secure their reservations at an early date from Dr. William Hale, Jr., 264 Genesee Street, Utica.

DELEGATES' DINNER

A dinner for the delegates will be served in the Hotel Utica on Monday Evening, May 14, following the adjournment of the afternoon session of the House of Delegates. Tickets \$1.50.

EDITORIALS

Defeatism

Subtle as smoke, insidious as vice, invidious as evil, festering as the plague, fearful as the knees of a coward, self-seeking as a politician, promising as the eyes of a coquette are the advocates of defeatism who again rear the Medusa of propaganda for the socialization of medicine.

Again is heard, ever more loudly, the voice of the false prophets crying: "It is inevitable—we must surrender or be lost—there is no standing against it—the odds are too great—the foundations with all their riches and influence are for it—the politicians are for it—the people have been taught to demand it—it must come—let us make terms—any terms before it is too late; before we are overwhelmed; before we succumb."

Thus the Caillaux' and Bolo Pachas of medicine to-day! Those of France in 1917 caused mutiny in the army, disorganization in the Government, despair in the people—almost the loss of the war. For what? For the money of the enemy of France! And until when? Until there arose to power one strong, brave and ruthless man who reanimated the Army and the Nation with truth, with courage, with steadfastness, and with faith.

Medicine in the United States needs a Clemenceau. Can it find one?

"Alice in Wonderland"

One of the major fallacies of the "brain trusters" of the medical foundations is the naive assumption that by legislative enactment the entire population can be regimented for medical and health purposes. There is no substantial evidence, either in history or current experience, that the entire population at any time and under any circumstances can be made to interest themselves in their health or their physical disabilities. It is a sad but recurrent experience for the attending physicians at hospitals to find gross medical conditions utterly neglected when the individual is in active contact with expert medical service and which is provided free of charge. Residents within one hundred yards of a hospital live for years without taking the trouble of walking next door in order to have their medical conditions analyzed and appraised. The recent activity of the Milbank Memorial Fund is suggestive of the superiority complex that seems to be permanently a part of the mental equipment of their personnel. On March 14, under the roof of the New York Academy of Medicine, the technical advisors, friends, well-wishers, curiosity seekers, and self-appointed tycoons of medical charity assembled and after round-table discussion came out with what was alleged to be a completely worked out plan for distributing medical service by means of compulsory health insurance. In the metropolitan dailies on Thursday, March 15, appeared an equivocal report of these round-table discussions, and an eager and alert public was allowed to survey Alice in Wonderland, looking through the mirror, at her socialized medical offspring.

The first ponderous suggestion from the self-anointed leaders of the medical revolution was that the provision of good medical care to all of the population is essential to the nation's well-being. It would be interesting to view the medical Columbus that discovered this fact. In like vein, quality of medical care should not be sacrificed to economy and cost, and those who render

medical care should be adequately remunerated. It was then proposed to set up an organization of a State Department of Medical Care; and then, like the spreading yew tree, this organization was to embrace a Board of Medical Care, Commissioner of Medical Care, Advisory Board, Deputy Commissioner, Judicial Counsel, Departments of Education, Investigation, Administration, Professional Supervision, and Finance. It is interesting, as a diversion, to note that in the pictorial representation of this scheme "finance" occupies the smallest allotment of space. There would be thus set up a bureaucracy for New York State, located at Albany, and with a complete regimentation of the physicians of this State, subject to local medical council and control boards. This grandiose scheme was to be financed by a compulsory system of group payment, for the "round tablers" in Paragraph 16 of their protocol stated "group payment for medical care should be grounded on the compulsory basis."

It was alleged that the entire cost of this compulsory health insurance would only be about seven dollars in addition to the annual per capita cost of medical service as set forth by the Committee on the Costs of Medical Care. The increment of seven dollars would hardly pay for the secretaries that would be required to acknowledge the complaints that would pour in on the central office from an outraged citizenry.

When the Committee on the Costs of Medical Care was spending its hundreds of thousands of dollars and acquiring such an accumulation of reports of doubtful authenticity, they failed to survey the most outstanding example of one of the forms of compulsory medical care. The Committee completely dodged the problem of workmen's compensation which had reached such a state of racketeering, corruption, division of fees, fake bills, fake conditions, that it was a menace to the public. The same Committee passed over contract practice which is probably the second largest item in the social application of medical practice to the community. It spent very little time on the known defects of health insurance in European countries. Nor did it take into its consciousness the

historical fact that when the remuneration in any given line of human activity passes below a decent standard of living the quality of that service deteriorates beyond measure. The same Committee was partial to the groups that it selected for a survey of group practice, and student health service was almost omitted. After the Report of the Committee on the Costs of Medical Care had died of inanition, a group of the self-same well-wishers canvassed the State and sought to make contacts with the various local clubs and Chambers of Commerce for the purpose of propagandizing for the revivification of the Report. To-day we see a recrudescence of the same impulse. A critical observer might question why the funds of the Milbank Memorial Fund are being expended in propaganda for an entirely new system of medical practice. Why the present system is literally to be "junked." Why no thought is given to the present financial difficulties of our hospital system and of our charity. Furthermore, the same observers might suggest that the Legislature of the State of New York should investigate the source of the funds of the various medical foundations and where these foundations are carrying on a banking business they should be subjected to the same taxation as applies to similar institutions engaged in like activities. It might satisfy public curiosity to know the primary source of the funds of some of the foundations and whether they are derived from monopolistic business practices.

We reluctantly come to the conclusion that the best interest of the citizens of this State would be served by a searching investigation as to the activities of all foundations which seek to mold or influence public opinion by propaganda. It is a tremendous responsibility for any self-constituted group of social reformers, a group of paid theorists set out to create a medical utopia, to set out to destroy what is a going concern which, with all of its disabilities, has functioned in the main adequately and effectively, or to destroy a system that has made such splendid contributions to the health and well-being of the citizens of New York State. What grandeur! What courage! "Grandeur,"

said Pangloss, Professor of Metaphysico-theologico-cosmolo-nigology, "is extremely dangerous!"

Denmark Conquers Syphilis

A notable milestone in medical progress is reached when any nation can record the fact that it has driven from its borders a disease that has plagued the race as terribly as has syphilis. A bulletin issued by the U. S. Public Health Service contains an article abstracted from a French medical journal entitled "The Virtual Disappearance of Syphilis in Denmark." The fight has lasted nearly a century and a half. Free treatment began in 1790, treatment was made compulsory in 1874, and free treatment became compulsory in 1906. These regulations have reduced the cases to a minimum, and most of the ones now seen come from abroad.

The measures are administered in such a way that no one can reasonably object to them. The patient can select his own physician and place of treatment, but treatment he must have. Infection of any other person is visited with heavy penalties. The practicing physician informs the patient of these regulations, and if he refuses treatment after two warnings, he is reported to the sanitary police. He then becomes a number in the police files, so that the filing clerks do not know the names of the patients. The filing system is so complete that a case can be followed up for years, with all details of treatment and results. All patients, high or low, rich or poor, male or female, of character good or bad, are subject to the same regulations. An effort is made to have the patients return for tests for several years after treatment, and the majority make no objection. The compulsory feature of the law is seldom necessary.

How far this plan would go in other and larger countries is, of course, an open question. Its success in Denmark, however, commands our notice. It is a plan that could be tried in a city, a county, a state, and, if successful, could be expanded to any larger territory as desired. It was Hamlet who remarked that there was "something rotten in the state of Den-

mark." If he were alive today, he would find that in one respect, at least, conditions are better.

Telephone Charge Adjustments

As a result of the editorial which appeared in the JOURNAL under date of February 15, we have been literally swamped with letters and telephone calls from members requesting that we handle adjustments and refunds on their telephone charges. Unfortunately our staff is not large enough to permit our rendering this service, much as we would like to do so. In the meantime we have also learned that there are several small independent telephone companies operating in various sections of the State of New York under rates somewhat different from those of the New York Telephone Company, and these particular companies do not extend the residential telephone rate to physicians who have their offices combined with their residences.

This editorial was instrumental in securing adjustments and refunds for several hundred, if not thousands, of doctors.

The Revised Food and Drug Bill

It is refreshing to find the Tugwell-Copeland Food and Drug Bill reported out of the Commerce Committee to the Senate with a full set of teeth still in it, and in good sharp condition, too, in spite of all efforts to file them down. Some alarm was felt by friends of the measure when the newspapers told of the organization of a committee of manufacturers to oppose it as "dangerous and un-American" because it gave the Department of Agriculture "bureaucratic control" over the food, drug, and cosmetic business. The only result of this opposition is the provision in the revised bill for an advisory committee with two of the seven members appointed from the food, drug, and cosmetic industries to consult with the Secretary of Agriculture in enforcing the law. Another change is the elimination of the list of thirty-four diseases prohibited in advertising by the original bill. "I never was keen myself about the section which listed all the

diseases," remarks Dr. Copeland. Other changes are of a minor nature dealing mainly with administration.

The chief object of the new bill is to plug the gaping holes in the old measure which permitted flagrant abuses. Take it by and large, it merely makes the manufacturers of foods, drugs, and cosmetics observe common honesty. It protects the public health against ineffective or downright harmful nostrums, and it protects their pocketbooks against paying \$1.50, for example, for 45 cents worth of horse laxative, or Glauber's salts, marketed under a fancy name. Honest manufacturers, too, are protected against the tricksters and shysters who would ruin their business by lying and fraudulent competition, and, it would seem clear to most people that they should lend their support to the bill, instead of organizing to oppose it.

Another advisory body is to be a Committee on Public Health, appointed by the President with a view to their distinguished scientific attainments and interest in public health. No member of the Department of Agriculture or anyone financially interested in the three industries affected, will be eligible to it. The medical profession is again recognized in the provision that a drug shall be deemed to be misbranded if representations on its label or in its advertising concerning its effect are not supported by "substantial medical opinion" or by demonstrable scientific facts. Honest differences of opinion may exist, but the Committee explains that the expression "substantial medical opinion" is "intended to mean contemporary opinion shared by some numerically significant group, including recognized experts in the field in question." Practitioners employed for the occasion by the unscrupulous are not considered to be in this category.

Just now, when advertisements of remedies for colds stare us in the face at every turn, it is especially interesting to notice that the bill provides that any medicine that is merely a palliative must bear a statement that it is a palliative, and tell how the palliation is effected. The Committee in its report remarks very truly that many consumers take the expression "for the relief of colds" to mean that the article is an

effective treatment for the disease itself. If the drug merely dulls the pain, reduces fever, or lessens congestion of the nose or throat, the user has a right to know it, so that he can take care of the diseased condition more intelligently and effectively, and not rely on a palliative.

Then, too, drugs containing habit-forming narcotic and hypnotic substances must have a label stating the amount and bearing the legend, "Warning—may be habit-forming." Under the present act merely the quantity has to be stated. This has proved to be not enough. Persons using such remedies regularly have become drug addicts. Now they are to be warned.

Common drugs sold under fancy labels and fancy names (at fancy prices) must carry the common name along with the other, so that the well-known practice of selling bicarbonate of soda or sulphur and molasses under some highfalutin title will have the mask torn off, at any rate. People who still insist on being fooled will have no excuse.

The bill goes even to the point of protecting people who may ignorantly take a good remedy in a wrong way. Some drugs are just as potent for harm as for good. Thus a patient with asthma may take a potassium iodide preparation to relieve his paroxysms, but if he has an arrested case of tuberculosis, the drug may render it dangerously active. Again, the last doses of a bottle of worm medicine given without shaking before each dose may be fatal to children because the potent principles settle out on standing. So the bill stipulates that a drug liable to such misuse must bear warnings on its label to prevent it.

The section dealing with cosmetics is a much needed addition to the present law, which has nothing on this important subject. Serious harm to health, and such injuries, indeed, as blindness and paralysis, have been caused by various hair dyes, eye-lash and eye-brow dyes, complexion bleaches, and depilatories. The mischief is due to toxic ingredients like certain coal-tar dyes and such metals as lead, arsenic, mercury, and thallium. The bill guards the public against further injury.

Only a short time remains before the close of this session of Congress. If the

editorial selection has swung far over to the original article whose title indicates a definite subject and whose reasoning is largely deductive. The detailed presentation of the individual case has largely disappeared. To be sure many articles are based on experience with groups of cases but the histories are often either left out or placed in subordinate type that many readers may "skip" without losing the continuity of the main theme advanced by the author.

Without for a moment suggesting that the present customs are unwise, or that editorial advice has not created a vast improvement in medical literature, the *Journal* believes that in all probability much material of true worth may be now encysted because unwelcome, in the files of many physicians. A carefully considered single case, intelligently presented, has values. It may inspire inductive thinking and may also, often, solve instantaneously a puzzle in the mind of a practitioner, be he a specialist or general family physician, who is confronted with a doubtful case. It can also provide later students of literature with additional authoritative data in their studies of special subjects.

To be acceptable for publication, such reports must, of course, pass a very strict censorship, and thus the Management Committee will provide Unusual interest, proper work-up, well chosen language, and brevity are essential. Authors should expect what might seem harsh treatment in order that actual publication may fulfill the objects that are sought.

Dr S. S. Goldwater, Commissioner of Hospitals, New York City, announces that economies and reorganizations, still only partly completed have enabled him to wipe out the \$552,706 deficit that was facing his department for this year. Besides this, the Commissioner declared, he has brought to an end the political influence which for years has been part of the hospital system. Many of the unneeded employees were put to work originally by order of district leaders, he indicated.

AMERICAN HEART ASSOCIATION

The American Heart Association will hold its Tenth Scientific Session on Tuesday, June 12, 1934, from 9 30 A. M. to 5 30 P. M., at the Cleveland Hotel Cleveland Ohio. The Program will be devoted to Arteriosclerotic Heart Disease.

Correspondence

Anonymous letters will not be noticed. All communications must carry full name and address of the writer, but these are omitted on request.

To the Editor

Ex Mayor McKee in his address at the Academy of Medicine states that the cost of public service in New York City has 'in the last twenty years doubled and trebled itself' and 'slowly but surely the government is assuming more and more the work of the private physician.'

It may be well to remember that in the last twenty years the cost of everything else has doubled and tripled and that any municipality, state, or government that engages in the practice of medicine should not complain of the cost of it. Instead of this being an argument for the state control of medicine, it should be judged as a good reason why they should not do it and to simplify and control the public institutions so that only the indigent poor are cared for, this also being necessary for the voluntary institutions. The fetish of cities, counties, states, industries, insurance companies, funds, endowments, hospitals, clinics, etc., to practice medicine is reacting on them. They should have considered the cost before they went into it rather than going right on to the detriment of both themselves and the medical profession. Paternalism is good but carried too far does harm. What the whole subject now requires is a wise dictator, a broad minded economic individual or policy and either the former Roosevelt square or the present Roosevelt 'new' deal. The shoes are pinching but the feet in them are not those of physicians but those of laymen, politicians and organizations. In the meantime the members of the profession are glorious, charitable and kindly while avalanches of propaganda on the high cost of medicine and the like are being hurled at them as if they were the culprits and responsible for the difficulties. The sooner our and other countries wake up to the fact that physicians can handle the whole subject more wisely and fairly to all concerned the sooner it will be straightened out properly. The health of the people is a public matter but it should be left in economics and activities to where it belongs namely the medical profession. All we want is the wherewith in hospitals institutions charitable organizations, etc., to help along and they can depend upon the many centuries old traditions of the profession to take care of the essentials. We have been under a code for twenty four hundred years and we do not need a lot of opinions from nonmedical sources to make one for us. Let those not in the medical profession take care of their own codes, which they certainly are not doing very well with. When they have been at theirs a few years and harmony is established among them under it they then can get somewhat of an idea of how it feels to be butted into from the outside. If they do as well with theirs, which was politically imposed as we have done with ours, which was voluntarily imposed, we may be in frame of mind to listen. In kindness, tolerance and charity the medical profession are continuing their work, but there are a lot of people who have taken it upon themselves to run our job for us. It is not in the nature of the medical man to fight back. We are too priestly for that.

But it is in our nature to want to be left to our own work and not to be interfered with or deprived of our rights as medical men.

ANTHONY BASSLER, M.D.

To the Editor:

The vicissitudes of life have made the physician's place in society quite precarious of late. Among the many reasons for it, the ever increasing flood of patent "cure-alls" has become a problem of the first magnitude. It were all well and good if people who want to doctor themselves were left alone to use grandmother's herbs. At best they would have a good purge, at the worst they might cause themselves a little stomach ache. In either case that kind of medication would do little or no harm. However, serious consequences to the health of the public ensue sometimes when the use of patent medicines is substituted for simple self-medication. That did not deter the patent-medicine makers from expanding the market for proprietaries by relentless advertising over the head of the physician directly to the public, until the use of patent medicines has grown to such proportion that their manufacturers now hold fully 85 per cent of the business of treating the sick which most properly belongs to the physician.

There is no use for the physician to wrap himself up in his toga of pure knowledge and allow himself, like the Caesar of yore, to be stabbed by the rabble. There is no sense in his ignoring the patent-medicine menace as being far beneath his dignity. It will do no good for him to suffer in silence and wait until he will have to drive a taxicab for a living.

Why not put up a fight, may one suggest? There is, fortunately, a choice of weapons. And since so much is at stake, each should be used to the limit. The stern fiat of the law, which has always been on the side of the physician, should be invoked. The support of the public should be sought. It could be had for the asking, for the public is tired of being constantly fleeced and at times poisoned by some of those patent "cure-alls." Advertising should be used, too. Conducted properly, it will work marvels. It is a truism that the flaming truth of knowledge will easily send up in smoke the fraudulent advertisements of the patent-medicine makers. Besides, the physician ought to cease prescribing patents himself, a practice which supports those who seek to bring him down and keep him there. Moreover, the physician has a natural ally, and quite a formidable one, the pharmacist, who is just as rebellious against the patent-medicine makers as the physician is.

"Descend from your pedestal, doctor," I would say to the physician, "and throw off your toga. Roll up your sleeves and put up a man's fight for the things you so dearly paid for. Stop prescribing patent medicines at once. Dust off your good United States Pharmacopoeia and National Formulary, and use them, for Heaven's sake, use them! It is your only salvation. Ally yourself with the pharmacist and put your combined strength into the sacred war for your places in the scheme of things and for the business that rightfully belongs to each of you. Together you are invincible. Together you cannot fail."

SPRING DIPHTHERIA IMMUNIZATION CAMPAIGN

THOMAS PARRAN, JR., M.D.

State Commissioner of Health, New York State Department of Health, Albany, N. Y.

A state-wide diphtheria immunization campaign will be carried on during the spring months of this year. Plans for such a campaign were discussed at a conference held in Albany on March 19 and attended by representatives of the various organizations who participated in the five-year campaign, including representatives of the State Medical Society. Slight increases in diphtheria prevalence, the low immunization status of certain localities, and the availability of extra nurses for house-to-house canvassing are among the reasons for embarking upon a special campaign at the present time.

DIPHTHERIA PREVALENCE.

Both diphtheria cases and deaths increased slightly in number in New York State, exclusive of New York City, last year.

During 1933, 710 cases and 65 deaths were reported, as compared with 654 cases and 59 deaths in 1932. Of themselves, these slight increases have no particular significance, but in view of the fact that diphtheria cases and deaths failed to decline in 1933 for the first time in five years, they are worthy of notice.

Also disturbing is the occurrence of several small, but explosive diphtheria outbreaks since the beginning of 1933. The majority of these outbreaks have taken place in the western or southwestern part of the State, but their occurrence has not been limited to these sections. Places in Albany, Jefferson, and Westchester Counties have also been visited by diphtheria epidemics within the past twelve months. Although no single outbreak has reached

COMMITTEE ON ECONOMICS

A Study of Medicine in Industry

Medicine in industry has been obliged recently to submit to economic situations. In many industries medical work has been done away with completely, in others the employment has been part time, the number of hours being curtailed. As conditions have made it imperative in some industries the physician has disappeared completely and the emergency treatment of sickness and accident carried on without any real medical supervision, in some instances by the trained nurse and occasionally by the untrained nurse. By and large, medical service in industry has been maintained rather more generally than would have been expected 25 years ago. A quarter century past even a slight economic flurry would have been responsible for the entire elimination of the physician and the medical department from any except those industries carrying with them extraordinary hazards, and where the medical work was absolutely indispensable to the conduct of the business.

Under present conditions, there is a definite increase in the interest on the part of management in the methods for the safe operation of business. It is plain to be seen, that this consideration has now gone beyond the phases of the industry associated with its mechanization, and the characters of the processes and materials used. More time and consideration is being given to the general subject of working conditions including job allotment, light, heat, ventilation, hours, rest, recreation, etc. Management has been thinking more intensely along these lines as a natural outcome, of the depression, aside from scant work and scant wages, which would be manifest in the form of various bodily and mental conditions. It is felt, that medicine in industry to-day is more than ever concerned with the problems of prevention, particularly as exemplified by working conditions, and those phases of the life habits of employees suitable for and available of supervision.

As a result of contact with a number of industries, we feel that the company physician still continues to occupy his recently improved professional position, and to augment his already outstanding field in

industry. Management has been reasonably sympathetic in meeting the problems of the present day, both from the standpoint of medicine as practiced within industry, and with respect to the employee in his sickness, accident, and rehabilitation contacts with the outside medical profession. The physician in industry, while in practically all instances compensated inadequately, when viewed in terms of the return of the successfully practicing physician, nevertheless, under present conditions, has been accorded a more adequate security than the physician in general practice. As a general thing, the physicians in industry while having received pay cuts with the rest of industry has been accorded as much consideration as have members of other outstanding operating departments.

It is felt by your Committee that the physician in industry is occupying a place, which social and industrial conditions have made necessary, and has received, and continues to receive, financial returns on a scale comparable in amounts to those paid for relatively new and developing forms of endeavor.

A Study of Practice of Medicine by Corporations

The practice of medicine by corporations, theoretically does not exist in New York State inasmuch as the law definitely says that corporations cannot practice medicine. Those interested in proving that the practice of medicine of the corporation type does exist must be compelled in each instance to assume a very difficult burden of fact finding. There are a number of industries where, in general, the letter of the law is complied with, and yet the provision of facilities for diagnosis and treatment may be otherwise interpreted. This appears to be particularly true during the development of the present depression, where certain industries have found it necessary to dispense with the services of physicians and are relying, for the maintenance of such medical facilities as they still deem needful, upon the industrial nurse. It would seem that here an element of liability must exist, even though the character of such services is in the majority of instances relatively simple. Most of the time, the rendering

of what is often considered unimportant medical service does not attract attention. However, the severe condition with mild symptomatology and an indefinite history will, from time to time, come under initial attention of this sort, with the result that only too frequently, conditions will be minimized, available time lost, and even disaster supervene.

The Endicott Johnson Company in New York State, as is well known, have felt it incumbent upon them to provide rather complete medical and surgical service, not only for employees, but also for members of employees' families. The same comment may be made of the Life Extension Institute, Consolidated Gas Company, Interborough Rapid Transit Company, and other large corporations. When it is attempted to apply the definition of corporate practice of medicine to what are deemed medical endeavors by these organizations, it is found that the physicians carrying on the work operate under their own responsibility. The medical departments in such corporations simply bear the title as such, and are not considered as a corporation's activity.

The terms "medical department," "medical office," "health department," and "health office," while construed by many to mean that these are departments operated by their respective companies, nevertheless indicate quite the contrary, and it is for the purpose of avoiding criticism under the legal meaning of the term "practice of medicine by corporations," that this is done. Where the nurse is the sole functioning unit in a medical office or medical department and is diagnosing and treating cases of disease, no matter how simple, there is no dodging the issue that such a nurse is practicing medicine, and under the law of the State of New York nurses cannot practice medicine. The acts which she may be carrying out, in company assigned space and on company time, while she is receiving remuneration from the same source might be understood to be the practice of medicine by corporations. Here again, there exists an element of doubt, in that the liability for unlawful acts must rest with the nurse. The fact that she is using company space and company facilities in the pursuance of her unlawful activity, even though she is receiving compensation from a corporation, does not mean that the corporation is practicing medicine. The physician operating under the same circumstances, must be con-

sidered as practicing medicine in his own right under the law, regardless of the fact that facilities are placed at his disposal, and that he is receiving compensation from the corporation. Furthermore, this is not modified by the fact that management can exercise a certain amount of control over his activity.

It is true, that in certain parts of the country outside of New York State company-conducted medical organizations are inevitable, as for example, in such districts as those served by the Colorado Fuel and Iron Company. The Laurentide Company of Quebec, and others, where the local community does not provide medical talent or hospital facilities. Sometimes these may become very elaborate and provide for the needs of the entire community as participants by virtue of their membership in the employment group of a particular company. Here again, the physician rendering the service may be operating entirely under the law and within his own rights.

As a result of the contacts of this subcommittee with various industries throughout New York State, and in other parts of the country, it is only the very exceptional medical endeavor that is operated under radical management, where controversial situations arise. In most instances, the medical organizations in the several businesses serve as clearing houses for the sick or injured employees. This is becoming a more and more prominent part of industrial medical service, and is a natural outgrowth of the fact that the sick employee is a charge against the business and in the end must be responsible for a certain amount of the cost of the product or service delivered by a particular business. This means that the providing of first aid and diagnostic facilities carried out by medical personnel, may have results that are reflected in the manufacturing or service cost. The committee finds that very generally the results of such diagnostic facilities are placed in the hands of community physicians by the very natural system of direct reference.

It is to the advantage of management, that employees receive adequate medical care, and the provision of diagnostic facilities functioning chiefly in the investigation of conditions ordinarily neglected by the employee, and the provision of medical advice that would otherwise not be sought, constitute a form of service decidedly to be encouraged. This would naturally lead to the reference of employees to capable

physicians The employee who is ill while on the job either is too sick to work, under which condition an effort should be made to find out the nature of the difficulty, and see that the individual is placed under proper medical supervision, or if able to continue at work, an immediate intelligent therapy should be provided, in lieu of the inevitable and often disastrous self-diagnosis and self-medication

Such industries as the Norton Company, Thomas Edison interests, Orange, N. J., the American Rolling Mill Company, Winchester Arms Company, National Harvester Company, the Hood Rubber Company, Bethlehem Steel Company, General Electric Company, Solvay Soda Process Company, and United States Aluminum Company, are fairly representative groups who maintain facilities for this type of medical service Their most prominent service is that making for early adequate diagnosis and the institution of adequate medical service for their employees This statement means the utilization of such medical services as are provided in the industrial communities and supplementing them as justified The medical organizations of these companies also spend a large part of their time on the periodic health examination and the maintenance of safe working conditions As a result of contacts with the medical officers of these organizations it is apparent that, while the continued treatment of disease is not the policy—even though inadequate emergency, medical, surgical and hospital facilities have prompted the institution of a more adequate service—nevertheless, they are still subject to criticism

It is the opinion of your committee that it would be exceedingly difficult to prove an instance of actual practice of medicine by one of these corporations according to the wording of the law There are groups of medical individuals organized under lay control which operate for profit, but where the physician must be considered as carrying on the practice of medicine as he is privileged under the law Instances of this kind exist in many organizations rendering nation-wide and even state-wide service, some purely as health conservation measures others offering service for the socially ill and industrially sick and injured, and even in the realm of physiotherapy, rehabilitation and vocational guidance

Under way at present are the following courses in nine Counties

COURSE ON TRAUMATIC SURGERY

arranged for Schoharie and Otsego County Medical Societies by Dr. John J. Moorhead

March 28 *Fractures in General*

Dr. Henry H. Ritter, 755 Park Ave., N. Y. City

April 11 *Intra abdominal Injuries*

Dr. Herbert Bergamini, 101 E. 89th St., N. Y.

April 25 *Joint Injuries*

Dr. Willis W. Lasher, 565 Park Ave., N. Y. City

May 9 *Fractures of Long Bones*

Dr. Joseph H. Gaston, 101 E. 89th St., N. Y. City

May 23 *Head Injuries*

Dr. H. V. Spaulding, 115 E. 61st St., N. Y. City

June 6 *Treatment of Hand Injuries*

and Wounds

Dr. David Goldblatt, 300 Central Park W., N. Y.

COURSE ON INFELCTIONS

arranged for St. Lawrence and Jefferson County Medical Societies by Dr. Frederick T. van Beuren, Jr., New York City

April 12 *Bacterial Invasion of the Human Body*

Dr. F. L. Meleney, 180 Fort Washington Ave., N. Y.

April 19 *Rheumatism*

Dr. F. M. Hanger, Jr., Presbyterian Hospital, N. Y.

April 26 *Infections of the Head and Arm*

Dr. Hugh Auchincloss, 109 E. 67th St., N. Y. City

May 3 *Puerperal Infections*

Dr. E. Everett Bunzel, 215 E. 72nd St., N. Y. City

May 10 *Infections of the Bones and Joints*

Dr. C. R. Murray, 180 Fort Washington Ave., N. Y.

COURSE ON TRAUMATIC SURGERY

arranged for Herkimer and Montgomery County Medical Societies by Dr. John J. Moorhead, N. Y.

March 29 *Fractures in General*

Dr. Henry H. Ritter, 755 Park Ave., N. Y. City

April 5 *Head Injuries*

Dr. Carl A. Peterson, 115 E. 61st St., N. Y. City

April 12 *Abdominal Injuries*

Dr. H. M. Bergamini, 101 E. 89th St., N. Y. City

April 19 *Fractures of Long Bones*

Dr. E. A. Dooley, 101 E. 89th St., N. Y. City

April 26 *Joint Injuries*

Dr. Willis W. Lasher, 565 Park Ave., N. Y. City

May 3 *Hand Infections and Wounds*

Dr. W. D. Ludlum, Jr., 115 E. 64th St., N. Y.

COURSE ON INTERNAL MEDICINE

arranged for Tioga County Medical Society by Dr. Luther F. Warren, Brooklyn

April 4 *Coronary Thrombosis*

Dr. George H. Roberts, 46 Sidney Pl., Brooklyn

April 11 *The Diagnosis and Treatment of*

Biliary Tract Disease

Dr. A. F. R. Andresen, 88 Sixth Ave., Brooklyn

April 18 *The Treatment of Cardiac Failure*

Dr. J. H. Crawford, 225 Lincoln Pl., Brooklyn

April 25 *Ulcerative Colitis*

Dr. John B. D'Albora, 27 Eighth Ave., Brooklyn
May 2.....*Pernicious Anemia*
Dr. Eugene Marzullo, 75 Remsen St., Brooklyn

COURSE ON NEUROLOGY

arranged for Steuben and Chemung County Medical Societies by Dr. Foster Kennedy, New York City

March 29.....*Description of the Nervous System*
—*Neurological Examination*

Dr. Abraham Kaplan, 73 E. 90th St., N. Y. City

April 5.....*Pathology and Clinical Neurology*
Dr. Lewis D. Stevenson, 410 E. 57th St., N. Y.
April 12.....*Diseases of the Spinal Cord*
Dr. Louis Hausman, 140 E. 54th St., N. Y. City
April 19.....*Epidemic Encephalitis*
Dr. E. D. Friedman, 1192 Park Ave., N. Y. City
April 26.....*Brain Tumors and Brain Injuries*
Dr. S. Bernard Wortis, 410 E. 57th St., N. Y.
May 3.....*Epilepsy*
Dr. Foster Kennedy, 410 E. 57th St., N. Y. City

SPECIAL ARTICLE

(Continued from page 380)

alarming proportions, the recent widely scattered series is to be regarded as a danger signal. In spite of the low general prevalence of the disease, diphtheria epidemics still may, and do, occur.

The probable source of only one of the epidemics mentioned could be determined. The others apparently arose from hidden sources, rather than from clinically recognizable missed cases. The number of apparently healthy carriers discovered in each outbreak exceeded the number of clinical cases, indicating that carriers played a large part in the transmission of the disease. The importance of carriers and missed cases as sources of infection in diphtheria is not fully appreciated by the public. As shown by many surveys in this and other countries, diphtheria carriers are numerous at all times in places of any considerable size. The public must be taught that exposure to diphtheria can scarcely be avoided and that artificial immunization is necessary regardless of the reported incidence of the disease.

PROGRESS IN DIPHTHERIA IMMUNIZATION

There are 13 New York State cities of 10,000 or more population in which 35 per cent or more of the children under five years of age have been reported as immunized against diphtheria on January first of each of the past five years. A list of these cities—that is, New York State's diphtheria immunization honor roll—is given below:

Auburn,	Middletown,	Port Chester,
Ithaca,	Newburgh,	Port Jervis,
Little Falls,	Niagara Falls,	Rockville Center,
Mamaroneck,	Ogdensburg,	White Plains.
	Ossining,	

Of the remaining 54 cities with 10,000 or more population, 27 have good diphtheria prevention records, but there are 20 cities where the proportion of children reported as immunized has never reached 35 per cent, and there are 7 other cities

whose immunization percentages have fallen from satisfactory to low levels. Special efforts are to be made in the spring campaign to improve the immunization status of the 27 cities belonging to the last two groups mentioned.

CAMPAIGN PROCEDURES

Special emphasis will be placed on house-to-house canvassing as a means for encouraging parents to have their children immunized. Experience has amply demonstrated that home visiting by nurses, or especially instructed lay workers is one of the best methods of securing the results desired.

Newspaper articles, radio talks, and other publicity methods will be used freely. Popular literature, cards for physicians' offices, and publicity material for local use will be available.

Efforts will be directed toward the protection of children less than five years old, because of the high diphtheria morbidity and mortality in this age group. The incidence of diphtheria in older children is so low that, except during epidemics, large-scale efforts to immunize them cannot be expected to prevent many cases or deaths.

The toxoid distributed by the State Department of Health is the immunizing agent now recommended for general use. It is further recommended that toxoid be administered in two doses of 0.5 c.c. each, with an interval of one month between doses.

The full cooperation of physicians throughout the State, such as was given in the five-year campaign, is earnestly requested this year. That another campaign is advisable has been shown by references to recent diphtheria outbreaks, and to the unsatisfactory immunization status of many communities. With the active participation of the medical profession, the success of the new undertaking is in a large measure guaranteed.

A STUDY OF DIABETIC DEATHS BASED ON AUTOPSIES

IVAN HLKIMIAN, M D and SAMUEL A VOGEL M D

From the Buffalo General Hospital and Buffalo City Hospital

We are to day confronted with a strange paradox, a continually rising death rate from diabetes despite the rather universal application of a specific remedy of proven efficacy. The medical profession is challenged, both by its natural interest and by the various comments which have been made, and are being made, in the lay press.

Statistics, which are readily available from the registration area of the United States, the City of New York, the Metropolitan Life Insurance Company, and various other sources, indicate that the death rates have been steadily increasing over a long period and that their progress has been affected very little by the advent of insulin. In the whole country diabetes is now credited with ninth place as the cause of death, the rate being 22 per 100,000. It is noteworthy that the death rate among children and young adults has been distinctly diminished in recent years, while among women, particularly those past the age of fifty, it has been definitely increasing.

The purpose of this study of 84 necropsy protocols is to add to the cases already in the literature and determine, where possible, the actual relationship of the diabetes to the cause of death.

For the reason that we believe that the above mentioned statistics may more or

less accurately indicate an increased incidence of diabetes, they do not necessarily reflect an increased mortality unless the actual cause of death in the diabetic is known. In other words, a patient's diabetes may contribute a varying and often an indeterminate element to the immediate cause of death.

The material which forms the basis of this report was gathered from the Buffalo General Hospital and the Buffalo City Hospital. It covers the period from 1923 to 1933. The data represent the opinions of several pathologists, who did the post mortem examinations in a routine manner without having had the present study specifically in mind. Therefore, we must make certain allowances for their interpretation of findings and for their qualitative descriptions.

DISCUSSION

Of the 84 necropsied cases (Table I), approximately 90 per cent were after the age of forty, which corresponds with the generally accepted view that diabetes is a disease of later life. The series is rather small to justify any mention of sex differentiation. However, 49 were males and 35 females. The average duration of the diabetes, as determined from the patients' histories, indicates that most of the patients

had the disease for some time, especially those in the sixth and seventh decades. If the total period of diabetes is computed in the 84 patients, we find that the sum equals 392 years. Only 24 of these patients had received insulin prior to their admission to the hospital. The total number of years of insulin administration in this group was 92. Presumably, many of the patients who did not receive insulin should have. The majority of patients in this entire group were in all probability treated haphazardly, if at all, and consequently do not represent an ideal state. Nevertheless, they undoubtedly represent a fair average of diabetic patients who have been admitted to a general hospital during the past ten years and, therefore, serve to demonstrate the pathology of diabetes.

COMA.—Twenty deaths from coma out of a group of 84 diabetic deaths is far too large. A great many of these occurred in the early insulin era and we believe that the mortality from coma would now be much less. Also, the majority occurred in the fifth decade; it is well known that the older person does not tolerate coma as well as the younger and that he is more apt to have irremediable complications.

TABLE III.—FREQUENT ADDITIONAL FINDINGS

Decade	1	2	3	4	5	6	7	Total
Coronary sclerosis.....	..	2	7	15	16	8	..	48
General atherosclerosis.....	2	5	10	6	..	23
Cholelithiasis.....	1	3	4	8
Cholecystitis.....	1	1

In a statistical study of deaths from coma by Dr. Louis Dublin of the Metropolitan Life Insurance Company on Dr. Joslin's cases, it was determined that during the pre-insulin period, 60 per cent of diabetics died in coma during the Naunyn period, whereas in the Allen era, coma was

responsible for 40 per cent of all deaths. In the early Banting period, the deaths from coma dropped to a little above 10 per cent, while later in the Banting period deaths from coma were further reduced to about 10 per cent.

ARTERIAL DEGENERATIVE DISEASES.—These comprise gangrene, coronary occlusion, general arteriosclerosis with hypertension, and cerebral thrombosis. They count for 28 of the deaths (Table IV). There was no patient whose death was caused by this means before the fourth decade. There were 2 in the fourth decade and 12 in the sixth.

TABLE IV.—SUMMARY OF IMMEDIATE CAUSES OF DEATH

Decade	1	2	3	4	5	6	7	To
Diabetes (coma).....	1	4	..	6	8	1
Infections.....	..	1	2	3	13	7	1	..
Arterial degenerative diseases.....	2	7	12	7	..
Carcinoma.....
Miscellaneous.....

Sclerosis of the coronary arteries was considered to be of sufficient grade to receive comment by the prosectors in 48 of the patients, all after the third decade, but notably in the fifth and sixth. We have no way of ascertaining accurately whether this sclerosis was beyond what would be expected in the nondiabetic; this point must be left to conjecture.

Concerning the incidence of *degenerative vascular disease*, it will again be noted from Dublin's figures that the frequency of vascular disease as a cause of death has been mounting as the treatment of diabetes has been improved. This is partly accounted for by the fact that diabetics are now living long enough to acquire nondiabetic degenerative diseases. Prior to 1924 Joslin found that his patients died at the average age of 49. Two years later this figure had climbed to 59, and one year later it had reached 60.9 years.

In this connection it is well to call attention to the increasing length of the average span of life. In 1900 it was 55 years. In 1930 this had been extended to 65. It will be seen in our series that 63 of the 84 deaths occurred after the fifth decade. It becomes apparent, then, that by making it possible for people to live longer, we have also increased their chances of developing diabetes. Thus, there has been created a larger number of potential diabetics.

INFECTIONS.—Under this heading are included patients who died of pyemia, abscesses and carbuncles, pulmonary tuberculosis, postoperative *B. welchii* infections, endocarditis with congestive heart failure, and syphilis (mostly cardiovascular). Thirty-three of the 84 met such a fate. In the case of *staphylococcus infections* there is no doubt that a patient with uncontrolled diabetes is a fertile field for such invasion and that this association establishes a vicious circle which is often impossible to break. Similarly, the diabetic, especially when the disease is active, is a very acceptable host for *tuberculosis*. Fortunately, this combination of diseases appears to be decreasing in recent years and tuberculosis often may be completely arrested by treatment. In general it may be said that the controlled diabetic is not much more, if any more, susceptible to infections than a nondiabetic.

It is interesting that but 3 of our group died of *malignancy*. One would expect a higher incidence in people of these ages. In fact, this seemed so striking that we were lead to review an equal number of necropsy protocols of nondiabetic subjects of the same age and found a much higher incidence of malignancy. Similarly, the association of gall stones and diabetes is reputed to be high. Our nondiabetic group showed a slightly higher frequency of this condition than the diabetic.

COMMENT

The diagnosis of diabetes is fairly easily made and probably it is rarely missed. Therefore, it is only natural that a death may be charged to diabetes where it does not specifically belong. In obscure cases

where there is no postmortem examination, diabetes may be given a too dominant place in the death certificate. Joslin has said that "diabetics are not immortal, although one would think that immortality was expected of them by statisticians."

We appear then to be facing an increased incidence of diabetes and consequently an increased number of deaths in people who are victims of this affliction. Various ideas to account for this have been put forth. It may be a combination of factors such as urbanization of our communities, the mechanization of our industries, the increased tempo and strain of our modern life, and the tremendous increase in sugar consumption. Bouchardat, a student of diabetes in the nineteenth century, admonished his patients by telling them "you shall earn your bread by the sweat of your brow."

SUMMARY

1. An attempt has been made to determine the cause of death in 84 diabetic patients by an analysis of necropsy protocols.

2. Degenerative arterial disease was responsible for one-third of the deaths. Infections accounted for slightly more than one-third. Coma, which was frequently complicated, was listed as the cause in 26 per cent. The remainder had miscellaneous causes.

3. The unfairness of attributing the deaths of all patients with diabetes to the diabetes itself is discussed. The rising reported mortality of diabetes concomitant with the rather universal use of insulin can only mean an increased incidence of the disease.

NINTH CONFERENCE OF THE INTERNATIONAL UNION AGAINST TUBERCULOSIS

The Ninth Conference of the International Union Against Tuberculosis will meet in Warsaw, Poland, on September 4, 5, and 6, 1934, under the chairmanship of Prof. Pieztrzynski. Reports will be made on three subjects as follows: "Biological Variations of the Tubercle Virus," by Prof. Karwacki of Poland; "Tuberculosis of the Bones and Joints," by Prof. Putti of Italy; and "The Use and Organization of Tuberculosis Dispensaries," by Prof. Leon Bernard of France. The representatives of the United States who will take part in the discussions are Dr. Esmond R. Long of the Phipps Institute, Philadelphia; Dr. Clarence L. Hyde of the Springfield Lake Sanatorium, East Akron, Ohio; and Dr. B. S. Pollak of the Hudson

County Tuberculosis Sanatorium, Secaucus, New Jersey. There will also be an afternoon lecture by John A. Kingsbury of the Milbank Memorial Fund, New York, on "Methods in Further Control of Tuberculosis." Delegates are expected from the 43 countries represented in the Union. An attractive program of receptions and excursions has been arranged and visits will be made to the chief antituberculosis institutions of Poland.

A special party is being arranged from the United States and for those who can leave in advance a trip to Russia is scheduled that will permit delegates to arrive in Warsaw in time for the meeting. Further information may be obtained by addressing the National Tuberculosis Association, 50 West 50th Street, New York.

THE MORTALITY OF ACUTE APPENDICITIS AS RELATED TO CLINICAL TYPES AND TREATMENT

JOHN J. WESTERMANN, JR., M.D.
New York, N. Y.

In a recent advertisement by one of the largest life insurance companies there is a statement that the death rate from appendicitis in the United States has increased steadily during the past ten years. It goes on to advise the layman, that: "performed without delay an operation for appendicitis is almost always successful. Be sure to consult an experienced and skillful surgeon because many needless operations have been occasioned by incorrect diagnosis." Surely this advice demands much of the average lay intelligence.

As a matter of fact, in 1921, The Equitable Life Assurance Society paid 7,743 death claims, of which 193 were on account of appendicitis—in 1931 it paid 12,043 claims of which 332 were on account of appendicitis. It may be assumed that any slight increase in this proportion could easily be accounted for by improved diagnosis.

About 25,000 people die annually in the United States on account of acute appendicitis, and it is estimated¹ that there has been an increase of 30 per cent in the mortality in the past ten years. On the other hand, in² England and Wales a steady increase in the occurrence of acute appendicitis and a substantial decrease in the number of deaths from this disease have been noted for the past fifteen years.

The weekly bulletin of the New York City Health Department for November 21, 1931, states that in 1910 in sixty large American cities the death rate due to appendicitis was 13.3 per 100,000 while in the same cities, without increase in population, the rate for 1929 had risen to 18 per 100,000. It goes on to state that there is a great sacrifice of lives and that this sacrifice deserves serious consideration.

The recent report³ of the mortality of acute appendicitis from a large southern city does not coincide with these statements.

It seems obvious that studies of acute appendicitis should be made regularly and brought to surgical attention with a view to a final standardization of treatment. One of the striking facts about this study of 500 consecutive cases performed by the several members of the Surgical Staff of

St. Luke's Hospital in New York City, is this standardization in the treatment. And, except for recent improvements in the postoperative care, it has persisted through the past fifteen years. The outstanding points in the treatment are: (1) Immediate operation. (2) Repeated frequent examination where the diagnosis is in question. (3) Operation where only one or two of the cardinal symptoms are present. (4) Drainage by the use of rubber dam only, entirely replacing the use of tubes and other methods. Ordinarily this drain is placed at the base of the cecum or in the pelvis. (5) Postoperative administration of fluids in every way and frequent use of transfusion.

The 500 cases upon which this study was based are consecutive admissions to St. Luke's Hospital during the years 1928, 1929, and 1930, and are cases which were proved to have either acute suppurative or gangrenous appendicitis by pathological examination: 92 of these were gangrenous, 304 were drained at operation, and 190 presented definite free purulent material in the peritoneal cavity. It should be noted that this does not include the mildly acute and acute catarrhal appendices.

Experience has taught the author that acute inflammation of the appendix is not at all times the same condition and that it may be classified into three separate and distinct groups, based on the history, pathological findings, and to a lesser degree the symptoms. The surgical treatment should be varied according to the group, and the prognosis may be very closely determined by this classification.

It will be evident that this attempted classification differs from that of Wilkie⁴ and others in that here the author does not divide the process in any case into its separate stages. It is not his opinion that perforation, kinks, and scars change the course of the disease in any way.

Group 1 includes those cases which are coincident with, or immediately subsequent to, respiratory and other acute infections elsewhere in the body. The disease is usually limited to the outer coats of the appendix and is presumably hema-

togenous in origin, and in no case has there been a history of previous attacks. Where cultures were obtained, they were invariably streptococci. The pathological examinations are strikingly similar and, for example, the author will quote from two reports as made by Dr Leila C. Knox: "there is an acute suppurative lesion with necrosis and hemorrhage throughout the wall. The muscle is edematous and swollen, the surface is covered with exudate, the mucosa, although hemorrhagic, is intact." The second is of an appendix removed during an attack of acute tonsillitis and exactly typical. "There is an acute suppurative process involving the entire wall. The mucosa is unusually well preserved, the epithelium showing active hyperplasia. The submucosa, however, is suppurating, the entire muscle is infiltrated and thickened and the surface is covered with granulations in which there is much purulent exudate."

To further illustrate this type a quotation from an operative record and also the pathological report by Dr Knox will serve. This patient was operated upon for acute mastoiditis ten days before, and death from general peritonitis followed the appendectomy, the culture from the peritoneum was hemolytic streptococcus. "The appendix was found free in the peritoneal cavity. It was injected and thickened, and although inflamed, it did not appear to be primarily the cause of the infection. The cecum was indurated, injected, and appeared to be the source of the trouble. Glands in this region were enlarged and inflamed." The pathological report states that, "the appendix is the seat of an acute suppurative lesion with much involvement of muscle and with focal areas of infiltration by polymorphonuclear leukocytes chiefly around the blood vessels. The mucosa is normal."

The bacteriological work done and reported by Rosenow, Borgen, and Haden from time to time is sufficient evidence that acute appendicitis may be of hematogenous origin, even though not all bacteriologists obtain the same selective organisms in their cultures.

We might place in this group also, the appendiceal disease which occurs in epidemics. Among others, Rosenow and Dunlap,⁵ in 1916, reported an epidemic of appendicitis and parotitis probably due to streptococci in dairy products.

Dorsey⁶ states, "that the relation of focal infection to appendicitis is definitely shown by the marked contrast between the degree of localization in the appendices of streptococci found in the nasopharynges of patients who had appendicitis and those who had arthritis."

It seems reasonable to believe that when streptococci cause acute appendicitis, it is of hematogenous origin, and that the lesions are entirely mural.

Of these 500 cases 83 could be placed in Group 1. On the basis of clinical, bacteriologic, and microscopic evidence the preliminary infection was tonsillitis in 25 cases, pneumonia in 10 cases, middle ear disease in 12 cases, acute rheumatic fever in 4 cases, and measles in 8 cases. Although the number of deaths in the entire series was 39, or 7.8 per cent, in this group of 83 cases the mortality has been conspicuously higher, namely, 16 deaths, or 17.1 per cent.

An analysis of this group shows that it is essentially a disease of younger persons, the average age being thirteen and one-half years, and that it is due to streptococci and infrequently staphylococci. One is impressed with the initial severity of the onset and the early appearance of general peritoneal involvement. Although paralytic ileus is a common sequel, ileostomy is fatal. Trauma and excessive operative interference in these cases accentuate the infection and interfere with the natural peritoneal resistance to the infection in most cases. An intramuscular incision should be the one of choice. Drainage with rubber dam should be instituted in the presence of free fluid. The appendix should not be removed if there is any difficulty experienced in the attempt. However, this occasion is not so frequent with the experienced operator. Ileostomy and any other secondary measures are very poorly tolerated and always light up the infection. Spinal anesthesia is useful in an attempt to overcome ileus. One cannot stress too strongly the early and copious administration of fluids including the large saline and glucose infusions and repeated blood transfusion.

In a second group are included those cases of appendicitis which are intrinsically of the appendix as a result of injury to the mucosa, with ensuing infection by organisms of the fecal type. This group may be classified primarily, by the pathological examination of the specimens and

to illustrate the writer will again quote from one of Dr. Knox's reports: "There is a dilatation of the lumen with atrophy of the coats, and with an added acute diffuse suppuration with much necrosis. The necrosis extends throughout the mucosa, and there is widespread infiltration of the submucosa with polymorphonuclear leukocytes and round cells."

As opposed to Group 1, these cases are not fulminating, general peritonitis is not an early complication, and in the cases seen three or four days after onset one is more likely to find signs of a localizing abscess in the right lower quadrant rather than a spreading peritonitis⁷ with probably a vaccination of the peritoneum.

Here one finds predominating digestive symptoms with a history of earlier attacks of a similar nature. Vomiting occurred in 90 per cent of the cases in this group. And the classical symptom, pain in the epigastrium, later radiating to the right lower quadrant, was present in 80 per cent of the cases in this group. This is the common type of appendicitis occurring in 372 of these 500 cases.

From this study it is evident that this type has a definite tendency to be self-limited with abscess formation, and that the mortality is, except upon rare occasions, due to excessive operative interference. In other words, in the majority of these cases, regardless of the duration of process (and we have records of some of two or three weeks' duration) peritonitis and death have been brought about by too radical efforts upon the part of the operator, together with a fixed determination to remove the appendix, regardless of the risk. A most valuable procedure, and one which is rapidly meeting with favor in the presence of abscess formation or localizing peritoneal involvement, is the induction of drainage at the site with a minimum of surgical trauma.

Incision and drainage only was carried out 16 times in this series and resulted favorably 11 times. It was done only where the prognosis was extremely poor and if we bear this in mind, the results are remarkable. It might be added that the patient should be advised that the appendix is not removed in such cases, and warned to seek surgical assistance in the event of another attack. Four of the 11 who recovered from the original attack returned to the hospital and were operated upon for acute appendicitis successfully from two

to six months following their original illness.

To quote from the operative records to illustrate just what is meant by death due to operation: "Local anesthesia was used, but nitrous oxide and ether had to be resorted to during the course of the operation. A McBurney incision was made. Because of difficulty in choosing the right place for the incision there was difficulty in locating the appendix. After the peritoneum had been opened the appendix was finally secured and tied off near its base with chromic catgut. No attempt was made to tie off the appendiceal artery nor to invert the stump. A drain was placed at the site of removal." The record of the gross pathological findings accompanying this operative record stated that "there was free pus exuding from the abscess, in the center of which lay a necrotic appendix." Operative time was one hour and twenty minutes. A reference to the following chart shows the close relationship between the mortality and the applied surgery in this group.

Of the 500 cases studied, 372 should be included in Group 2 by the history and pathological report. There were 18 deaths in this group, in actual numbers, but 2 more than in the first group, or a mortality of 4.1 per cent, demonstrating the relative benignancy as compared with the first. Furthermore, the age incidence in this group was 30.6 years, whereas the hematogenous type apparently was more or less limited to younger individuals.

A résumé of the tabulation of the deaths in this group accentuates the facts that: first, a right rectus incision was used 11 times (always making for a prolonged operation with more exposure of the peritoneum) and second, that ileostomy (again prolonging and increasing peritoneal exposure) was used 5 times.

Group 3 includes those cases which occur chiefly in older people. The average age of the 45 cases in this series was 56 years. It is characterized by a slow onset, with general digestive symptoms, and with the physical signs centered in the lower abdomen from onset. It occurs where the appendix has been the seat of previous inflammation and presents⁴ physical deformities which favor the occurrence of inflammation. The mortality is higher, chiefly due to the age incidence and lack of resistance to operation in persons who present the usual physical deficiencies of age.

Age Sex	Duration	Incision	Path Report	Culture	Cause
34 Male	96 hours acute arthritis	Intramuscular with drain	Acute suppurative	Hemolytic cocci	General peritonitis
23 Male	72 hours	Right rectus with drain	Acute suppurative	Hemolytic cocci	Paralytic ileus and ileostomy
47 Female	120 hours following tonsillitis	Intramuscular with drain	Acute suppurative		General peritonitis
2 Female	36 hours during acute bronchitis	Right rectus with drain	Acute suppurative		General peritonitis
7 Male	9 days during convalescence from mastoid operation	Intramuscular with drain	Gangrenous	Hemolytic cocci	General peritonitis
13 Male	24 hours with acute bacterial endocarditis	Right rectus with drain	Gangrenous	Hemolytic cocci	General peritonitis
34 Male	96 hours onset with pneumonia and chill	Intramuscular with drain	Acute suppurative	Hemolytic cocci	General peritonitis
41 Male	48 hours	Right rectus exploration with drain	Gangrenous	<i>Streptococcus viridans</i>	General peritonitis acute toxic degeneration of liver (autopsy)
14 Female	6 days with acute tonsillitis	Intramuscular	Acute suppurative	Hemolytic cocci	General peritonitis
17 Male	24 hours after tonsillitis onset with chill	Intramuscular drainage would probably have altered outcome	Acute suppurative		Death followed post-operative attempt to drain wound of general infection
10 Female	1 week during acute arthritis	Intramuscular with drain	Acute suppurative	<i>Staphylococcus aureus</i>	General peritonitis secondary hemorrhage
10 Female	24 hours with pharyngitis	Intramuscular with drain	Acute suppurative		General peritonitis
6 Female	5 days during course of pneumonia	Intramuscular with drain	Acute suppurative	Hemolytic cocci	General peritonitis
21 Female	48 hours	No operation, too ill	Gangrenous (autopsy)	Hemolytic cocci	General peritonitis
2 Female	48 hours with bronchitis	Right rectus with drain	Acute suppurative	Hemolytic cocci	General peritonitis
38 Male	24 hours	Intramuscular with drain	Acute suppurative	Hemolytic cocci	Mechanical obstruction on 5th day ileostomy on 9th day, death on 10th day
55 Female	48 hours	Intramuscular with drain local anesthesia	Acute suppurative	<i>B. coli communis</i>	Peritonitis difficult operation
19 Male	1 week with abscess	Right rectus drainage and ileostomy	Gangrenous	No growth	Peritonitis operative time 1 hour 32 minutes
34 Male	48 hours	Right rectus drain and ileostomy	Gangrenous	<i>B. coli communis</i>	General peritonitis ileostomy on 4th day with death 24 hours after
40 Male	5 days	Intramuscular drainage without removal of appendix		<i>B. coli communis</i>	Peritonitis delay due to incorrect diagnosis
42 Female	48 hours	Intramuscular with drain	Gangrenous		Peritonitis and pyonephrosis
39 Female	72 hours	Right rectus with drain	Gangrenous		General peritonitis
17 Female	24 hours	Intramuscular with drain	Acute suppurative	<i>B. coli communis</i>	Peritonitis ileostomy for ileus
2 Female	72 hours	Right rectus with drain	Acute suppurative		General peritonitis pyelophlebitis
13 Male	4 days	Intramuscular with drain	Acute suppurative	<i>B. coli communis</i>	General peritonitis secondary abscess of liver
49 Male	48 hours	Right rectus with drain	Acute suppurative		Appendix torn in attempted removal with profuse intra abdominal hemorrhage, death in 60 hours with temperature 106°F
50 Female	1 week	Right rectus with drain	Acute suppurative	<i>B. coli communis</i>	Exploratory operation general peritonitis
6 Male	1 week	Right rectus drainage and ileostomy	Acute suppurative		General peritonitis long operative procedure death in five hours
23 Female	24 hours	Intramuscular	Gangrenous	<i>B. coli communis</i>	General peritonitis paralytic ileus difficult operation with partial removal of appendix base was not ligated
19 Male	48 hours	Right rectus with drain	Gangrenous		Peritonitis secondary pelvic abscess ileostomy
32 Male	5 hours	Intramuscular with drain	Gangrenous		General peritonitis
21 Male	72 hours	Right rectus with drain	Acute suppurative	<i>B. coli communis</i>	General peritonitis paralytic ileus ileostomy

Age	Sex	Duration	Incision	Path. Report	Culture	Cause
39	Female	48 hours	Right rectus drain	rectus with Gangrenous		General peritonitis ileostomy
50	Female	24 hours	Right rectus drain	rectus with Acute suppurative		Thrombosis left femoral artery amputation left leg
60	Male	24 hours	Right rectus drain	rectus with Acute suppurative		Postoperative collapse of lung
64	Male	96 hours	Right rectus drain	rectus with Acute suppurative	<i>B. coli communis</i>	General peritonitis
62	Male	48 hours	Intramuscular drain	with Acute suppurative	<i>B. coli communis</i>	General peritonitis
52	Male	2 weeks	Right rectus drain	with Gangrenous		Intra-abdominal abscess coronary and common carotid thrombosis (autopsy)
67	Male	72 hours	Intramuscular with drainage only	local Patient moribund at operation		

There were only 45 cases classed in this group, of which 5 died. There is a marked tendency in this type to abscess formation, and of the 22 cases in which the duration was over four days, all presented palpable abscesses on physical examination. It is in this type that drainage of the abscess, preferably under local anesthesia, with a minimum of operative exposure, will reduce mortality markedly.

It is of general interest to note that 393 vomited at least once prior to operation and 387 gave the history of onset with epigastric pain, later radiating to, and becoming fixed in, the right lower quadrant. The average age of the entire series was twenty-two and one-half years.

Ninety of these 500 cases consulted a doctor prior to admission to a hospital, and in only 11 cases was there delay in establishing a diagnosis. Three hundred and sixty-one took some form of cathartic, showing that this form of home remedy is very popular for pain in the abdomen. However, the author believes, in this connection, that the harm from this medication lies in the delay in calling for medical attention while waiting for the expected benefit from the potion.

Ileostomy was used either with the primary operation or as a secondary procedure 9 times, and 7 of the patients died. The 2 cases which were benefited by this procedure had very definite signs of mechanical ileus. The others had either paralytic ileus or were exceedingly ill as a result of the disease. The author's experience leads him to believe that the recent enthusiasm for ileostomy is ill advised. However, it has a definite, though limited, surgical value in the presence of mechanical obstruction. Transfusion of blood,⁶ long infusions of saline and glucose, and administration of fluids by other means are the only forms of treatment to be exhibited

in the presence of general peritonitis and a dynamic ileus. The duodenal tube is very useful in the treatment of the nausea and vomiting accompanying peritonitis.

Spontaneous fecal fistula occurred but twice in this series and each time proved beneficial. Both were operated upon for closure before leaving the hospital. In one of these cases mechanical obstruction was present on the fourth postoperative day and the improvement following the occurrence of the fistula was most striking.

In no case was any attempt made to lavage the peritoneal cavity at operation with any germicidal agent either highly colored or clear.⁹ It has not proved of value in other hands.

The appendix was not removed primarily in 16 cases, of which 11 cases recovered. When it is considered that each of these was in most serious condition, the results argue well for the procedure.

To conclude, the mortality from acute appendicitis can be definitely lowered by the use of extreme care and gentleness at operation. The smallest exposure, compatible with the expedient removal of the appendix and adequate drainage makes for the smoothest convalescence. And furthermore, drainage alone, where it is recognized that removal of the appendix will be difficult, is an extremely useful procedure.

CORONARY DISEASE AND ITS RELATION TO THE INCREASE OF CARDIAC MORBIDITY

LOUIS FAUGLRES BISHOP, M D

and

LOUIS FAUGLRES BISHOP, JR., M D

New York, N Y

It would be hard to overestimate the far reaching effect of coronary thrombosis on the history of the world at the present time. When President Coolidge was needed to lead our country and they sought him for re nomination, he said, "I do not choose to run." He might have said, "I am threatened with coronary thrombosis and, therefore, I must not run." His recent death, presumably from coronary thrombosis, was only another of the many dramatic episodes that have characterized the history of coronary disease. A few days ago the man who had been selected as Attorney General of the United States fell a victim to it, and I would not like to begin to name the prominent and important men who have been stricken by it because I would never finish.

Instances such as these and the consideration of diagnosis in everything that pertains to acute stages of the disease have occupied much attention of late years. It seemed worth while, therefore, to consider the amount of illness that can be traced to coronary disease, apart from its acute manifestations. The recent increase in the number of people who are reported to die suddenly of heart disease accompanied by severe pain, or of acute indigestion, as it is sometimes called, is very noticeable. These represent the times when coronary disease for the moment occupies the center of the stage.

What we wish to study at this time is the large group of people who are afflicted by the discomforts and perils that are involved in the deterioration of the arteries of the heart. The tendency of the times is to classify a heart condition according to the cause rather than according to the particular pathology of the structures involved. Thus, chronic myocarditis, cardiosclerosis and cardiac atrophy may well be marked back to impaired circulation due to blood vessel disease.

The typical man attacked by coronary thrombosis is usually a man 57 years of age, well built and of the active, intellectual type. He is a man who would meet any emergency as it should be met, and his

reaction to even a condition so severe as coronary thrombosis is very different from what it would be in another type of person. One day this man is a central figure in a great business or profession, the next day he has succumbed to the most sudden and agonizing disease that we know. But beside the tragic occurrence, there may have been weeks and months of coronary stenosis with its warning, mild angina or breathlessness on exertion. For many years we have tried to read into the pathology of the heart muscle the causes of these symptoms. Now we know that when they develop in otherwise healthy people they usually mean coronary stenosis, with the ever present danger of coronary thrombosis. All attacks, however, are not so severe and many a person after a mild attack of coronary thrombosis has gone on with an impaired circulation in his heart muscle.

We have made a small statistical study of the last nineteen examples of acute thrombotic episodes which we have observed. This is relatively easy to do.

DATA ON 19 CASES OF ACUTE CORONARY THROMBOSIS

Age and sex	40 to 50	50 to 60	60 to 70	70 to 80
Male	2	8	4	4
Female	1			
Youngest, 42		Oldest 74		
Relation to angina pectoris, 15				
History of cardiovascular disease in family 9				
Duration of life following attack ranged from 2 days to 2 years in 11 cases				
<i>Recovery</i>				
Complete, 3				
Complete except for slight residual pain 1				
Recovered from acute attack, still in bed 1				
Residual pain on exertion, 1				
Residual pain on exertion or emotional stress 1				
Marked loss of myocardial reserve paroxysmal dyspnea occasional slight pain 6				
still present 1				

The task that we set ourselves—to estimate the amount of coronary disease and its resulting illness apart from coronary thrombosis—proved more difficult than we expected. It is like arteriosclerosis itself in that it begins in most people rather early in life and advances as a physiologic process. This was proved by the careful pathological examination on many comparatively young men who were killed in the world war.

Coronary stenosis in its lesser degrees must exist in all examples of general arteriosclerosis. So we have a large number of people converging to severe coronary stenosis, some of whom will pass into the group of coronary thrombosis.

The progress of medicine is a constant repetition of the processes whereby groups of sick people, apparently suffering from the same disease, are finally divided into smaller groups that are differently explained. Coronary disease has now been taken out of a group where it was frequently classed as "acute indigestion."

In reviewing some of the ancient books on medicine, we have found that people suffering attacks of coronary thrombosis were often believed to have been poisoned. One can easily imagine at a time when poisoning was one of the attacks by enemies that a person seized with great agony, finally dying, might easily be supposed to have been a victim of an enemy. Even up to the present time coronary attacks have been interpreted as ptomaine poisoning. And often to-day the polite name for coronary thrombosis is "acute indigestion."

The appreciation of the intracardiac circulation as influencing the functions of the heart obviates the necessity for the so frequent use of the term myocarditis. This term when abused arouses a feeling of resentment in the minds of thoughtful cardiologists. No one can force himself to believe that an active structure such as the heart can be the seat of inflammation for a long period of time. Inflammation in such circumstances would shortly terminate in recovery or otherwise.

Another term that was formerly used a great deal is not heard any more, fatty degeneration of the heart. In studying the morbidity of coronary disease we must decide what portion of people who formerly had suffered from myocarditis and fatty degeneration are now to be included among those impaired by defective coronary circulation. The profession has not only gotten away from the too free use of the terms "myocarditis," "cardiosclerosis," and "fatty degeneration" but now uses the term "coronary sclerosis" which indeed is more precise, representing as it does the etiology of the impaired heart.

From time to time we observe a practically complete recovery after a typical attack of coronary thrombosis. We recently published in the *Journal of the American Medical Association* electro-

cardiograms of one patient, covering a period of twelve years. The person is still alive and now shows the electrocardiogram following a severe attack of coronary thrombosis many years ago. We have many others not so vividly recorded, but no matter how severe an attack may be, there is always hope of complete recovery. Three years ago a man had an attack of coronary thrombosis so severe that after morphine failed to stop the pain, in the name of humanity chloroform had to be used to relieve his agony. He lay for months with a feebly functioning heart, but he has now returned to active business.

Is the increase in coronary disease due to any change in the disease itself or to a change in the group of persons affected by it? Let us look at this question.

Epidemic diseases vary in intensity between one epidemic and another, and even endemic diseases such as syphilis or tuberculosis vary in their malignancy—apparently irrespective of the condition of the people affected.

With coronary disease it is different. The condition of the arteries is dependent upon the metabolic processes affecting the whole organism, and in turn these metabolic processes are influenced in a large measure by the hygienic habits of the people.

Not only typhoid fever but other severe illnesses, such as influenza, pneumonia, rheumatism, or gout, may upset metabolism and institute the onset of arteriosclerosis.

It would seem that an influence tending toward the increase in coronary disease is to be found in the changed food habits of modern times, particularly in the great cities. The rich foods are so abundant and people's habits of eating are so luxurious that a large percentage of people are overfed.

Alcohol apparently has its effect only by increasing the food intake by stimulating the appetite.

The proteins of milk seem to be free from a tendency to produce arteriosclerosis. A notable evidence of this is found in the prolonged lives of people who get most of their proteins from milk products.

The existence of diabetes in people who develop arteriosclerosis is probably coincidental in that the same group is the group that would otherwise develop arteriosclerosis.

The same is true of hypertension for,

like diabetes, it is incidental to the same group that develops arteriosclerosis. However, hypertension hastens the development and increases the hazards of arteriosclerosis.

Some clinicians may fall into the foolish error of ruling out arteriosclerosis because they cannot feel hardening of the radial artery or because the temporal arteries do not show themselves. As a matter of fact, the observable changes in these arteries do not encroach on the lumen and are of little clinical importance. The place where arteriosclerosis is important is in the smaller arterioles that cause obstruction in the circulatory bed.

The occurrence of arteriosclerosis and hypertension in members of the same family is interesting. It happens quite often in brothers, coming at about the same age and with about the same degree of circulatory degeneration. Occasionally, husband and wife are under treatment at the same time.

The hereditary tendency is undoubtedly very strong. Some families live much longer than others. However, in the short-lived family we often find a single individual living to a great age; this one will tell you that all his relatives died young. The probability is that, apart from heredity, the fact that people from the same group are subjected to the same habits of life, eat the same food, drink the same wine, and carry on the same habits of work and recreation, contributes to this result.

Arteriosclerosis will be prevented when we know enough about foods to determine which ones are suitable for the metabolic abilities of each individual, and when food is strictly adjusted to the person—just as an internal explosion engine runs best on the right mixture, which varies with different engines.

The prevention of coronary disease must therefore be the prevention of the general arteriosclerosis or arteritis of which coronary disease is a localized manifestation. Some years ago after intensive study in connection with the writing of a book on arteriosclerosis certain conclusions seemed to be justifiable. Fundamentally, we are dealing with a general disease badly named, for its principal manifestation is a disease with which most people are in a degree afflicted but which a few escape.

A few years ago a man was examined by us who was supposed to be 156 years

of age. He seemed to be absolutely free from any taint of arteriosclerosis.

Coronary disease will be found less often when society has been so adjusted that people can lead happy and care-free lives, and are interestingly engaged continuously in suitable activities, with no temptation to seek relief from worry and strain in excitement and dissipation.

It has seemed to me that very old people that we have known have on the whole had a happy childhood and youth and have had a pleasant outlook upon the world. As a rule, the people who have undergone hardships in early life have not survived to a happy old age.

When we first took up electrocardiography and made it a systematic habit to observe every person who came under care, we began to see examples of what we then called "bundle branch block," naming the disease after its resulting physiology rather than its cause. At that time this was considered quite a curiosity, and in 1920, we presented to the New York Pathological Society for their discussion a group of 28 of these tracings. However, in the text of the paper we said that most of these were examples of coronary thrombosis. It has been a very long time since we looked over these records, and we are rather surprised how little out of date they are. The same electrocardiograms presented to the Society at the present moment would be diagnosed as "coronary disease," laying the emphasis where it should go—on the etiology rather than upon the changes in the electrocardiogram. It is true though that bundle branch block can occur from other conditions than coronary disease. We have seen complete obstruction of the bundle of His cleared up on mercury and iodide, when probably due to a gumma, and we once made a very careful study of an old man suffering from Adams-Stokes disease, where a calcareous nodule was found obstructing the bundle. For that reason we must not go too far in writing coronary disease into all electrocardiograms showing what appear to be characteristic changes. Having fought earnestly for the recognition of electrocardiography as a practical part of clinical medicine, we do not want to see our victory spoiled by being carried too far.

All medical opinion is subject to tidal changes, just as the waters of the earth ebb and flow under the influence of the

moon. We cannot say that the moon causes this flux of the brain mass of the medical profession. The moon is not timed right but there may be some other heavenly body that revolves around the earth about once in ten years that causes the ebb and flow of the medical mind mass. Over a period of about five years medical opinion grows in a particular subject and reaches its climax during the next five years, and then the matter becomes an unemphasized routine and something else has taken its place. At the moment we seem to be nearing the climax of interest in coronary disease, and some of the opinions that we hold now are certainly not true but an astonishing proportion of them seem to be unquestionably fact.

As a matter of caution we would like to recite an experience of a week ago. A gentleman supposed to be suffering from coronary disease was sent to one of us because it was suspected there might be something wrong with the diagnosis. The patient, presenting himself, complained of precordial pain and pain in the left arm. He gave a history of having been seized by severe pain in the lower chest and down the left arm. He had been kept in bed eight weeks. He brought with him an electrocardiogram, showing an inverted T wave in the third lead, but nothing else could be found wrong on careful analysis—discounting the fact that the electrocardiogram was taken when the patient was under excitement and the string was perhaps a little loose.

The clinical diagnosis of coronary thrombosis had been made and had been supposedly confirmed by this electrocardiogram.

A careful analysis revealed the fact that the pain in the arm was pretty constant and of an aching character, that it was not increased on exertion and was not relieved by nitroglycerin. This made us suspicious that an error of diagnosis had been made. So we decided to re-take the history though it had already been written out as a matter of office routine. The wife who was present casually remarked that her father had died a short time before of the same disease.

We found that this man who was suffering from a rheumatic diathesis, with some involvement of the endocardium and who had some impairment of the kidneys, had been present and witnessed the illness and death of his father-in-law with what

seems to have been a typical example of coronary thrombosis. Shortly after this experience, the subject of our story had a severe attack of rheumatic pain and some digestive disorder. This then supplied subjective symptoms that, on account of the profound impression this man had received, was projected into so good an imitation of an attack of coronary thrombosis that it had deceived his medical attendants. We found, in fact, that he had just as much rheumatic pain in his right arm as he had in his left, but his mind was so centered on his left arm that he ignored that in his right.

As a matter of policy the man was told that at the moment he had no evidence of coronary disease and that he could consider that passed, but that he should be treated for his rheumatism and his kidneys as he had received sufficient treatment of his coronary disease. He was allowed immediately to return to his work.

We have seen other astonishing examples of imitative coronary disease.

We speak of coronary disease but clinically we must often mean a condition in which there is complete obstruction of at least one branch of the coronary artery. It is obvious that before this happened there must have been degeneration of the arteries and a period when the circulation in the arteries was impaired; certainly partial obstruction at the mouths of the coronaries is very common.

We certainly need more, as it were, of a bird's-eye view of coronary disease, considering it from its beginning and its effect—even when thrombosis does not occur. The commonplace is always more important than the unusual. The condition of the coronaries should be appraised in every heart problem presenting itself after middle life.

Coronary disease, when resulting in acute coronary thrombosis involving a considerable area of the heart, is so striking and dramatic an episode that it tends to overshadow interest in the narrowing and hardening of the coronary arteries which ordinarily precede this event and preclude the calm contemplation of the place of coronary disorders in heart disease as a whole. This is so because, while coronary thrombosis constitutes a condition with the most striking symptoms, coronary disease has barely any symptoms at all, and those symptoms that it has it shares with many other conditions.

By inference, we can draw the conclusion that coronary disease exists when there is a generalized arteriosclerosis, but in the absence of the electrocardiographic evidence of silent and symptomless, small thrombotic episodes, it is hard to prove the presence of *coronary stenosis* in any given heart. However, the cardiologist who has thoroughly studied the heart patient from every point of view will be able to appraise, though not measure, the degree of coronary involvement. Even in the presence of an acute, painful thrombotic episode, one may be very much mistaken as to the extent of the damage. A mild attack may have destroyed an amount of heart tissue involving the danger of rupture of the heart, while in a much more severe attack as measured by pain, there may be but a small lesion.

It is not so easy to predict what symptoms are to be expected from narrowing. The blood supply to the structure of the heart must necessarily be diminished or at least unstable under these circumstances. And here comes to me a difficulty that has always arisen in my mind when structural damage or degeneration has been attributed to poor circulation and that is, the question whether functional or structural damage results from a circulation that falls below the maximum but not below the minimum which will supply sufficient blood to the part. In other words, is enough blood supply sufficient? Is not the blood supply of the body vastly in excess of actual necessity? My own belief is that it is vastly excessive and that a sufficient blood supply to the heart muscle is all that is necessary—as far as its nutrition is concerned.

On the other hand there are strong arguments to prove that the functional activities of various structures in the heart are actually controlled by a regulation of their blood supply. One will do well to read Geraudel's book¹ in this connection.

The study of *prethrombotic coronary disease* is a difficult task. Whenever any generation of doctors throws overboard the beliefs and teachings of their predecessors in wholesale manner, they are generally wrong. Therefore, in saying that coronary stenosis is a better term than myocarditis or cardiosclerosis, we do not wish on every occasion to disclaim the older and highly descriptive terms. But if it is true that the impaired nutrition of the heart is caused by impaired blood supply,

we are certainly in the line of progress in using a term founded on etiology. Certainly cardiac symptomatology suggests cardiac circulation as its basis.

The fact is that persons with weak hearts can often do a lot more if they start gradually and work up to exertion than if they start suddenly. This would seem to mean that the cardiac circulation must have time to establish itself in the face of obstruction. We have often said to people, "Do not run for the street car—walk around the block first." It is the sudden strain on impaired arteries that brings out their dysfunction rather than prolonged effort of less intensity.

There are no symptoms of the prethrombotic stage that are not shared by many other diseases, except perhaps attacks of purely functional angina pectoris, but even in this we must always suspect that there has been some degree of thrombosis.

When people have attempted to give the symptoms of the prethrombotic stage they have always mentioned irritability, easy fatigability and easy exhaustion of strength, and it is true that we do get this previous history from a large number of people after thrombosis has occurred; many have been under strain but have kept up in spite of these symptoms.

The consideration of the prethrombotic stage is the consideration of arteriosclerosis in general and must be cared for along the line of diet, rest, exercise, systematic use of castor oil, and the development of a sound philosophy of life.

These studies of the circulation of the heart have upset the relatively simple conception that satisfied us for many years that the distress on exertion was due to diminished pulmonary circulation, and we did not draw any very close distinction between pain in the front of the chest and shortness of breath. It may be well, therefore to distinguish between a painful oppression in the front of the chest on exertion and dyspnea on exertion that involves air hunger.

The absence of a recognition of the symptoms of impaired function of the coronary arteries short of obstruction, has held back the appreciation of the importance of the disease for many years, for all pathologists of experience were quite familiar with the appearance of occasional instances of obstruction of the coronary arteries with degenerated heart muscle and occasional examples of aneurysm of

the ventricles—some of which had even ruptured. These were shown as curiosities but their importance was not recognized in connection with every-day clinical medicine.

That functional adequacy is as much related to circulation as it is to structure is illustrated by many examples in every part of the body: kidney function can be perfect with very small kidneys compensated by increased circulation. Functional response on the part of the blood vessels to meet the demand of functional activity on the part of organs is what fails during the prethrombotic stage of coronary disease, and this apparently gives rise to irregularities of rhythm and difficulties of response to the demands of exercise.

A. previously existing hypertension has been regarded as the most common causative factor in bringing about thrombosis of the coronary arteries. This is not entirely true, for we see coronary thrombosis in people who have been observed for a long period of time and who did not have hypertension. We do not believe that hypertension is the cause of coronary sclerosis, any more or less than it is the cause of sclerosis of other arteries. To be sure, the arteries of the heart take part in the general hypertrophy of the circulatory system that grows out of the continuously maintained blood pressure, but in the large hypertrophied heart found in this type there is no evidence of impaired circulation, and many of these people are remarkably free from cardiac discomfort.

The marked and persistent fall of blood pressure after coronary thrombosis is hard to explain on a purely mechanical basis. Shock contributes at first, but after shock has passed it still continues. May it not be a protective phenomenon to spare the damaged heart?

Some years ago we published a short note in the *Journal of the American Medical Association* on the analogy between the important arteries in the heart and the similar arteries in the brain, and we called attention to the experience of a person who, at the same time, had an attack of coronary obstruction and an attack of hemiplegia.²

It is frequently encouragement to people who have had an attack of coronary thrombosis to tell them that this happened to them rather than an attack of cerebral apoplexy. There is indeed a close relationship, and we wonder if the relative increase of morbidity in coronary disease has

been accompanied by a decreased morbidity in connection with the arteries of the brain. If that should be found to be the case, we must look for some factor that has favored the heart rather than the brain as the seat of the terminal accident. Of course, we must not forget that the embolic phenomena may account for the hemiplegic symptoms; but that happens usually later.

An interesting fact is that people always think of apoplexy as due to ruptured blood vessel, and an attack of the pain in the heart as due to obstructive blood vessel. As a matter of fact, many cerebral accidents are due to thrombosis—with much the same findings as are present in the heart.

It would be contrary to the history of medicine to suppose that the intensive publicity given to this condition at the present time should not lead to many erroneous diagnoses and the waste of much valuable time on the part of sufferers who are detained in bed for weeks at a time. Personally we have always erred, if anything, in early liberation of patients—even after an acute attack of coronary disease. In this way we are sure that we have saved much mental suffering, and in suitably selected individuals among the victims of coronary thrombosis, we have seen no harm come of it.

In regard to a very prolonged rest period after coronary thrombosis, we are not in agreement with those who make it an absolute routine. We think that each sick person must be a law unto himself.

A certain number of people in one attack of coronary thrombosis are destined to die suddenly shortly after from another attack. Of course, if we keep all of our people with coronary thrombosis in bed from six weeks to three months, we will escape blame for those who die suddenly during this period. But if these attacks are due to a new and entirely unrelated attack, or if they are due to a giving away of a wall of a heart that is hopelessly damaged (which, of course, is a very rare happening), are we not subjecting a large number of people to unnecessary hardship to save ourselves? The writers know they have always erred on the side of the early convalescence of people after heart attacks, and by good luck they have seldom had reason to regret it.

As a group, heart patients are in danger of death, but they are also in danger of invalidism and we honestly believe that

for many people invalidism is worse than death. The moral, physical, and financial damage from unnecessary imprisonment of people who have been sick cannot be measured. In people of ample means, this is mitigated somewhat by systematic massage, and the nicety of their surroundings. Many people settle this question themselves by refusing to "stay put."

The prolonged rest period is founded on the belief that this way we escape the danger of rupture, the danger of more extensive thrombosis and also on the belief that the healing of the heart is promoted. It seems obvious that a heart heals better when its activities are curtailed, but that does not mean that it is true. In fact, the reverse may be true—that the heart heals better when somewhat more active.

Hearts have been beating for millions of years, and it has never been possible to demobilize them for the sake of having them heal. Is it not possible that in a hundred million years the heart has acquired the ability to heal itself without demobilization, and if so, does a little activity more or less make any difference?

Leaving out the protection of ourselves from possible blame, we believe it is our duty, instead of prolonging the period of invalidism, to shorten it as much as possible, after a thorough reeducation of the victim as to the nature of the disease and the precautions he must take. Not a small part of this education is the training in the use of nitroglycerin; this is a laborious matter but very essential.

The ideal of complete cardiac comfort in the presence of scars of coronary thrombosis is often too much to expect. The person must be taught to live with the heart he has.

Therapeutics is not part of our subject, but the tendency to pain can be diminished

by the use of theobromine and sodium salicylate and the influence of castor oil on the gastro-enteric tract.

In conclusion, we are led to believe that the increase in those who are recognized as suffering from heart disease has been greatly enhanced by a knowledge of the functions of the coronary arteries. The number of people now listed as heart disease instead of indigestion must be very great, and also we must add those who formerly would have been considered as suffering from a long list of conditions, such as asthma, liver disease, kidney disease and so forth. Certainly a better knowledge of coronary disease has been a large factor in initiating studies that have placed emphasis on the heart where it belongs. A survey of this matter leaves no doubt whatsoever in our minds that coronary disease is a very important element in the increase of cardiac morbidity at the present time. The life insurance fraternity seems to hold the same view. There are a vast number of men in all parts of the world centering their attention on this problem, and we can look with confidence to an appreciation of its early beginning and discovery of methods of prevention and cure.

We have inquired of various insurance companies as to the incidents of coronary disease. Although because of forms of tabulation required, the statistics were incomplete, it seems that the companies are paying about 2 per cent of their claims to people following definite and recognized coronary thrombosis.

THE BULLETIN OF THE AMERICAN SOCIETY FOR THE CONTROL OF CANCER

The Medical Society of the State of New York takes a very keen interest in anything which would tend to increase the knowledge of cancer among the physicians of the State. The Society thinks that the above mentioned *Bulletin* is a very useful instrument for this purpose. It contains a number of short practical articles written by distinguished authorities in the field

of cancer therapy and cancer research. It offers, at a subscription price of only \$1.00 per year, an easy and practical way for the physician to keep abreast of cancer control progress. The *JOURNAL* is informed that a complimentary copy of the *Bulletin* will gladly be sent to any physician requesting it from the American Society for the Control of Cancer, 1250 Sixth Ave., New York.

ACRODYNIA

L. de MELLO, M.D., and JAMES R. WILSON, M.D.

Syracuse, N. Y.

Synonyms.—Infantile acrodynia, pink disease, vegetative neurosis, trophodermatoneurosis, neurovegetative syndrome in infants, erythro-edema, trophoneuroses probably due to infection, polyneuritis syndrome resembling pellagra, Swift's disease, erythema epidemicum, cheiropodalgia, erythema polyneuritis. Any disease with such a variegated nomenclature usually means a lack of actual knowledge of its etiology, or at least some disagreement among different observers, and that is the case in this peculiar and interesting disease. The term acrodynia is probably the most commonly used, and not a bad one when one considers that the most striking symptom is painful extremities.

History.—From 1828 to 1830 the French reported an epidemic of a certain syndrome quite similar to what we know to-day as infantile acrodynia. Since that time similar epidemics have occurred in Sweden and England, but which have been traced to the presence of arsenic in beer or wine. The infantile acrodynia which we know is probably a different entity from the adult acrodynia. At least we have not yet reached the stage where infants may be suspected of arsenic poisoning in wine or beer.

Our first acquaintance with the disease as seen in children is rather recent, only forty years as observed in Australia, and only for the last 15 years in this country. In 1903 Selter in Germany reported a series of cases of a disease which he called trophodermatoneurosis which answers the syndrome to-day known as acrodynia. Our attention is always drawn to the Australian physicians who were the first ones to observe a long series of cases. Swift of Australia, in 1914, was the original observer, and since then many others. In the United States we have in 1920 the report of Bilderback of Oregon, although Byfield of Iowa City had a paper in 1917 to be read at the meeting of the A. M. A. which was not read because of illness. In 1920 he published his series of 17 cases. Since then many other cases have been reported, but the interest in these 2 cases here reported is that we have two children with acrodynia in one family, and subse-

quent recovery after certain dietary deficiencies were corrected. The only probable clue to the etiological factor was the lack of certain types of food usually considered necessary for child development. We do not offer these as the actual cause, but as suspicious elements in these 2 cases, and wish to record them as further guide to future investigations.

Etiology.—Let us discuss the different etiological theories in this disease. We have to date three main possibilities: first that we may be dealing with a disease produced by some disturbance in certain elements in the food necessary to body development. This may be covered by the modern and euphonious term: avitaminosis, a word which may mean much or little, but anyway, gives us a footing upon which we can stand to start our discussion.

There are many diseases caused by dietary deficiencies, and as classical examples we may cite pellagra and beri-beri. In acrodynia we have certain changes in the nerve tissue which resemble those found in pellagra, and it is of interest to note that Findlay and Stern were able by removal of certain foods from the diet of young rats to cause a condition similar to that seen in acrodynia. In their experiments all the known vitamins were available, and this suggests that the absence of certain varieties of foods may be the cause more than certain specific vitamins. In the treatment of this disease addition of fresh food, yeast, cod liver oil, fruit juices is the main part of the treatment. Raw liver given to the rats produced a cure. Wyllie and Stern used raw liver diet in human cases with success. The main histological changes in the nerve tissue consist of degenerative changes in the peripheral nerves, disappearance of the myelin sheath of certain nerves, and a chromatolysis of the cells of the anterior horn cells. Warthin found that the changes in the skin and nervous system suggested the pathology of early pellagra. The changes in the skin are also identical with those seen in certain forms of light sensitization.

The second theory is based on the fact that most of the patients with acrodynia

suffer with evidence of some disturbance of the upper respiratory tract, with a congestion or inflammatory condition. This usually lasts through the early part of the disease. Some cases have been reported to have been cured after tonsillectomy, but this has not been verified by the majority of observers. One wonders whether these patients got well in spite of the tonsillectomy,

balance of the vegetative nervous system. That theory is so mysterious and alluring that unless we have real definite proof that such a state actually exists the less said the better, as undoubtedly this theory has led us into many pitfalls as we are dealing with a condition about which we know so little. But we do have nevertheless some symptoms such as the excessive

Fig. 1.—Case E. G. Acrodynia. Showing (1) papular eruption on hand; (2) hemorrhage beneath skin on central aspect of left forefinger tip; (3) intense redness of tips of fingers (this is marked but does not show up well in this photograph).

Fig. 2.—Case E. G. Acrodynia. Showing hemorrhage beneath skin of forefinger (left).

Fig. 3.—Case E. G. Acrodynia. (1) Hemorrhage beneath tip of left forefinger; (2) patchy areas of redness on palm. These areas started a small reddish area then became larger and coalesced. They are present on both hands and both feet.

sweating and change in the temperature of the hands and feet, which may suggest some relation to the vegetative nervous system, and so, ad infinitum, almost every conceivable theory has at some time or other been advanced.

REPORT OF CASES

CASE 1.—E. G., girl, age 2. Admitted to University Hospital on June 21, 1930. Seven weeks prior to admission the toes showed a yellowish area around the nails of the large toes. Shortly the skin around all the toe nails became a bright red. Feet very cold; unable to get them warm. Patient well before this. Very irritable at the onset, very restless. At the end of two weeks tips of fingers and toes red. Rash, small red patches according to mother, appeared on abdomen which soon cleared up, but the other symptoms persisted. Marked

to my, as this happens so often in other diseases. To date we have nothing definite to prove that it is infectious, although the possibility still remains open.

The third theory is that of a disturbed

perspiration; clothes became soaked with perspiration day and night. Itching of hands and feet from the beginning. Temperature then about 100° to 102° F. Glands of neck visible. Appetite very poor from beginning. Patient seemed to squint as if light were unpleasant. Mother says that there has been considerable loss of hair. Examination on admission showed the following salient points: Dermographia present. Lips very red. Pharynx red, injected, and considerable gray mucus. Tonsils very large, red, and cryptic. Cervical lymph nodes on left side enlarged and tender. Fine papular rash, generalized. Tips of fingers and toes of an intense red color. Palms and soles present reddish areas of irregular size and shape which

the same as on admission. Ruptured vesicle on finger has not healed.

July 1. Feet and hands less red. Papular eruption has faded to a considerable degree. General condition better.

The feeding history of this child is interesting. Breast for 3 months followed by water-milk mixture. For a long time afterward child was fed largely on milk. Seven weeks before admission she was weaned from the bottle. At this time great difficulty was experienced in getting her to take solid food. Prior to that time she seemed to enjoy the milk, but would take little else. Never had cod liver oil, orange juice sometimes. Cereals only occasionally. During the past winter main article of diet was milk,

Fig 4—Case E. G. Acrodynia. Reddened area on calf of left leg, also ankle of right leg. They started out as a flat reddened area in the skin. Shortly afterward papules appeared.

Fig. 5—Case E. G. Acrodynia. Papular eruption on abdomen.

blanch on pressure. Similar area 1 in. in diameter on right thigh. Excessive perspiration. Marked pruritus of hands and feet. Very slight desquamation over palms and soles.

June 22. Papular eruption more marked, macular lesions have become larger. An extravasation of blood appeared beneath skin of tip of left forefinger, and became a large vesicle.

June 24 Throat condition subsiding. Cervical lymph nodes smaller. Patient less irritable.

June 25. Vesicle on finger has ruptured. Patient still very restless and irritable. Holds head down on chest. Pruritus still very marked. The skin manifestations and general condition showed an improvement with an improvement of her throat condition.

June 28. Lips dry and cracked. Ulcerations on inner side of lower lip. Right labia slightly larger than the left one. Skin and mucous membrane reddened. Considerable itching. Rash on abdomen entirely gone. Feet and hands about

1 to 1½ quarts daily, potatoes, peas occasionally. No green vegetables. Some fruits

June 20. Wassermann neg. R. B. C. 4,550,000 W. B. C. 17,200, hemo. 65 per cent, polys. 44 per cent, lymphos. 49 per cent, large monos. 3 per cent, basophiles 4 per cent.

June 26. Urine normal.

July 2. W.B.C. 20,000 with 50 per cent polys. Throat and nose cultures showed only normal flora. Therapeutic measures consisted of liquid diet when throat condition was at its height. Subsequently she was just on the ward diet with cod liver oil to supply vitamins A and D, vitavose to supply vitamin B, fruit juices for vitamin C. Was forced to take green vegetables and cereals.

Patient was discharged from hospital on the fourteenth day following admission. The whole picture gradually faded, and irritability decreased. During the month of October there was a re-

currence of some of the previous symptoms. It is interesting to note that at this time the child developed a so-called head cold, and tonsillitis. The redness of toes and fingers returned, irritability reappeared and a definite dislike for most of the articles of food developed. She was again returned to her normal diet and the symptoms gradually disappeared. To date there has not been any recurrence.

CASE 2 A G, age 3, sister of Case 1. During the month of July, 1930, child developed a cold, and extremities became cold, and reddened. Some irritability also appeared. These all faded within three weeks.

The feeding history of this patient is not as remarkable as that of her sister, although she always refused to take milk. Some milk was taken in the form of cocoa.

Two points stand out in these two cases. Both showed some history of sore throat in conjunction with the appearance of the symptoms of acrodynia; one patient showed a definite dietary disturbance.

GREENLAND HEALTH CONDITIONS

WARREN L. DUFFIELD, M.D.

Senior Surgeon St John's Hospital, Brooklyn, N Y

Greenland is so isolated from the rest of the world by location, by climate, and by government regulation that a few observations upon its health conditions, fragmentary though they are, may be of passing interest.

It was the writer's privilege to spend a few weeks this summer in Godthaab, Holstenborg, and Julianehaab on the west coast of Greenland, and in Angmagssalik on the east coast, as a member of the Pan American Airway-Lindbergh Expedition. A few days were also spent in Iceland.

Though Greenland is the largest island on the globe, Australia excepted, only a very small area is habitable, the remaining eighty-six per cent being buried by the inland ice which in places reaches a thickness of 10,000 feet. That portion capable of sustaining life consists of a narrow mountainous coastal area one hundred miles wide at its widest part and entirely absent in places where the inland ice reaches and enters the sea as glaciers. Where a strip of land does exist it is cut up in a most confusing fashion by deep fjords passing from the inland ice to the sea. Such a terrain makes communication extremely difficult and at certain times and places practically impossible.

The Eskimo population is about 16,000 and there are about 300 Europeans, the latter mainly concerned with matters of administration. In the far north the

Eskimos exist as nomadic tribes but toward the south many live in or near the few small settlements maintained by the Gronlands Styrelse or Greenland Administration.

Greenland is a Danish colony and "the principal objects of the Danish Government in its dealings with Greenland rest upon the double basis of developing trade and improving the living conditions of the Greenlanders and bringing them into contact with the best of what civilization offers. The latter purpose has been so successfully attained that the Greenlanders may be regarded as among the few primitive peoples who not only have not succumbed to the detrimental influences of civilization but have made such progress that at no far distant time they will be able entirely to take care of themselves."

The above quotation defines the policy of the Gronlands Styrelse and in carrying out and enforcing this policy they have maintained strict regulations in regard to permitting foreigners or even their own people to enter the country. These rules are rigidly enforced and there are perhaps few if any other places in the world where a constant quarantine is so efficiently maintained.

Our inability to speak Danish made it impossible to obtain medical information in some places and so the major portion

of the following observations are based upon statements made by Doctors Kristensen and Svendsen of Godthaab.

Tuberculosis is very prevalent, affecting all ages and practically every tissue of the body except the skin. It is responsible for a large part of the surgery, in the treatment of tuberculous abscesses and ulcers, though appendectomies and herniotomies are performed from time to time.

The habitation of the primitive Eskimo—a small sod hut—is, of necessity, most unsanitary and doubtless has been instrumental in spreading tuberculous infection. The Gronlands Styrelse is very actively encouraging the building of modern and more sanitary wooden houses. Another important factor in the dissemination of tuberculosis is the habit of the older women, many of whom are tuberculous, to chew upon pieces of seal, walrus, or other meat in order to make them more tender and then to give them to the small children to eat.

In Godthaab there is a new hospital of thirty-five beds which they expect will soon be filled very largely with tuberculous patients, naturally to the exclusion of other patients.

Cancer is apparently extremely rare. Doctor Kristensen stated that he knew of but one case, that of a cancer of the uterine cervix.

Infantile paralysis is endemic with serious epidemics occurring from time to time and quite a number of crippled children are seen. The local physicians feel the need of more specialized orthopedic treatment than they can give but hesitate to send these paralysis victims to Copenhagen for such treatment because of the high mortality from tuberculosis among those who are sent to Denmark. The change of climate seems to change the latent into active cases.

Measles, scarlet fever, and diphtheria are unknown, but whooping cough exacts a mortality rate of close to 100 per cent in infants up to two years of age.

Uterine fibroids are neither common nor rare, and those which are discovered are usually small.

Typhoid and dysentery occur at times, and also influenza. During the winter when there is no communication with the outside world the general health is good with only a moderate number of cases of pneumonia but following the arrival of the first ships in the early summer there is a

marked increase in the number of cases of upper respiratory infection.

Labor is usually normal and few complications are encountered. Special stress is given to training the nurses in obstetrics so that they may act as midwives. The nurses, by the way, are Eskimo girls who go about their hospital duties clad in the customary seal skin pants and soft seal leather boots or kamiks. This native dress is also worn by the maids in the households of the government officials.

Gonorrheal infection is present but it was not spoken of as being unduly prevalent. Syphilis does not occur except in one district which has been under quarantine for thirty years.

The diet of the natives is almost wholly meat—seal, walrus, whale, reindeer, wild fowl, and fish. Bread is a great luxury and they may have a little sugar at times but practically never any fresh vegetables. In spite of this diet nephritis and cardiovascular conditions are unknown, as is also diabetes.

Among the Eskimos who live "native" on the diet above described dental caries never occurs but the women's teeth become sensitive by middle life because of being worn back to the gum line by chewing on seal and walrus hide to soften it in the making of boots.

Few Eskimos attain the age of seventy and old age pensions are granted to them, by the Danish Government, at the age of fifty-five whereas in Denmark the minimum age is sixty.

The life of the Greenland doctor is in no sense a sinecure as they have to cover several hundred miles of peculiarly difficult territory. Sick calls are brought to them by men in their kayaks—boats made of seal skin stretched over a wooden framework—and they follow back along the coast or up the fjords in a motor boat.

In Iceland the health problems seemed to be the same as those of any northern European country with the possible exception of leprosy. A leper hospital was erected in 1897 and soon filled with eighty patients. There are but eighteen patients now remaining, and there have been but very few admissions for several years past. Chaulmoogra oil is the treatment used.

Reykjavik, the capital of Iceland, has a thoroughly modern hospital, of one hundred beds, heated by water from one of the very numerous hot springs which abound in Iceland.

PHYSICAL THERAPY IN THE CHRONIC INVALID

I. M. LEAVY, M.D.

Montefiore Hospital, New York, N. Y.

The status of the chronically ill has become a serious problem to the physician and community, for statistics show that as the average duration of life increases, so does the proportion of the number of persons with chronic disease.

The mortality rate from infectious disease in recent years has been markedly decreased, but there has been a continuous increase of chronic diseases in those who have survived middle life.

Boas and Michelson¹ have emphasized that the problem of the chronically ill and chronic diseases is a definite challenge to the physicians and to social and health workers; and that these patients are regarded as useless derelicts rather than as patients who need medical attention.

Though a most important consideration must be given to many of these patients in the matter of hospitalization, nursing and home care, yet very much can be done by physical therapeutics.

A report on chronic diseases by the Department of Institutions and Agencies of New Jersey,² of 2,199 chronic patients in five representative counties gives some very interesting information. There was an increased number of males, 51.3 per cent, to females, 48.7 per cent, and 50 per cent of the most common chronic diseases were:

Cerebral hemorrhage* and other	
paralysis	17.4 per cent
Diseases of the heart.....	17.0 per cent
Arthritis and rheumatism.....	12.1 per cent
Malignancy	6.9 per cent

The survey discloses the important fact that contrary to customary belief, chronic disease is not mainly a problem of the later years of life, and showed that almost 20 per cent of the patients were less than 40 years of age, and 12 per cent between the ages of 16 and 39, and that of these 63 per cent were totally, and 37 per cent partially incapacitated.

The report concludes that by far the larger group is receiving insufficient care, and it presents a real obligation to the community. Lack of treatment facilities is responsible for retarding or eliminating recovery or improvement.

The chronic invalid goes through a very long, trying period, not only by the long duration of the illness and its effects on the patient, relatives and friends, but the lack of encouragement offered by medical consultants. There is an obligation to these patients, and much can be done for them. When a patient is termed "chronic invalid," it serves to discourage all hopes of the patient and effort at rehabilitation by the physician.

In the early stages of chronic illness, the patient is able to perform his duties, but later leads to more or less incapacity. Though there are no ultimate cures for these diseases, yet their progress may often be limited, patients made comfortable and given many years of satisfactory life.

These chronically ill are among the most difficult for physicians to treat because of the long duration of their ailments, but these victims need the medical advice, encouragement, and sympathy of the physician to help them carry on.

The value and effect of physical therapy on these patients depend essentially upon the concise understanding of the patient's condition and the proper indication and application of treatment.

Swaim and Kuhns³ state that the ideal of therapy in any disease is a restoration of anatomic structure and return of normal function; unfortunately, this is rarely obtained in arthritis (one of the examples of chronic disease). The slow onset of the disease, with extensive pathological changes before treatment is sought, makes the realization of such an ideal difficult.

Cure comes only by gradual improvement in general health and by increasing the resistance of the patient.

Dr. W. J. Monaghan⁴ has said that too often it is assumed that these types of patients are incurable and beyond hope, when it is unquestionably a fact that many can be improved or even restored to such an extent that they can provide for themselves fully or in part.

We should recognize this responsibility and care of the chronically ill and help counteract the disastrous effect it leaves in the individual as well as his immediate family and on the community.

Many patients suffering from chronic

* Cerebral hemorrhage has 96 per cent of the cases in age groups of 40 and over.

of the following observations are based upon statements made by Doctors Kristensen and Svendsen of Godthaab.

Tuberculosis is very prevalent, affecting all ages and practically every tissue of the body except the skin. It is responsible for a large part of the surgery, in the treatment of tuberculous abscesses and ulcers, though appendectomies and herniotomies are performed from time to time.

The habitation of the primitive Eskimo—a small sod hut—is, of necessity, most unsanitary and doubtless has been instrumental in spreading tuberculous infection. The Gronlands Styrelse is very actively encouraging the building of modern and more sanitary wooden houses. Chaulmoogra oil is the treatment used.

Reykjavik, the capital of Iceland, has a thoroughly modern hospital, of one hundred beds, heated by water from one of the very numerous hot springs which abound in Iceland.

sheet anchor of the chronic invalid for his future life.

It is obviously impossible to discuss here each of the physical therapy agents and their technic of administration, or to enumerate each of the chronic diseases in which physical therapy may be of value. There are many forms of physical therapy which are of especial advantage in the hands of some physical therapists, or in which certain distinct modalities are preferable to others. The importance lies only in the results attained.

Ultra-violet irradiation, both local and general, has a definite place in the treatment of certain chronic conditions because of its effect on the blood pictures with the increase of red blood cells, white blood cells, and hemoglobin, and other constituents of blood, including the activation of vitamin D and increase of body calcium and phosphorus. Many patients with diseases accompanied with cachexia, inanition, avitaminosis, secondary anemia (such as accompany extrapulmonary tuberculosis) will show marked benefit by general body irradiation over a period of from one to three months. The systematic application of ultra-violet rays will enhance the effects with the administration of iron in secondary anemia, and liver in pernicious anemia. It may be safely said that general body exposure to ultra-violet irradiations is indicated in all cases of chronic bone and joint diseases.

Locally, in the air-cooled, water-cooled, or cold quartz burners and electrodes we have an efficient means for the treatment of indolent ulcers of the skin or mucous membrane, recent draining sinuses, and decubitus, so common in chronic diseases of neurologic origin. These are also applicable to certain resistant chronic skin diseases. Ultra-violet irradiation is not well tolerated by the aged and advanced cardiac diseases, particularly with marked decompensation; also in neuroses; and in diseases with severe cachexia, inanition, diabetes mellitus, and such skin diseases as eczema, psoriasis, and lupus erythematosus.

Low-voltage currents in the form of galvanism, faradism, and sinusoidal, find a ready indication in paralyzed or paretic muscles, due to upper- or lower-neuron involvement or of traumatic origin. They give neurogenic nutrition and power of contractility to those muscles which may, or may not, undergo atrophy from disuse.

The tonus of muscles will be either maintained or increased by the simple contractions by the current and produce mild heat and increased metabolism.

In combination with other measures, it will influence the effect on paraplegia of myelitis, neuritis, peripheral vascular and vasomotor changes, and atony of the abdominal wall and intestinal tract. It should be avoided in myasthenia gravis, neuritis with acute exacerbation, and it should never be applied in the region of the precordium.

Static electricity has a very limited field in the treatment of chronic diseases, but is superior when used in combination with other modalities. In the form of static waves or sparks, it will exert a penetrating effect on the deeper tissues of the spine and lower extremities of tabetics, peripheral neuritis, periarticular tissues of chronic arthritis, or in those with fibrous union, myositis, and bursitis. Local static treatments should not be used in hypertensive cardinals.

For the physical therapeutic treatment of chronic diseases, we rely especially on the important standard trio of physical therapeutic measures which are usually combined in their applications, namely, heat, massage, and exercise. Whatever objections there may be by medical men for instituting physical therapy, these three modalities are rarely ever interdicted. They lend themselves with advantage to the vast number of chronic diseases, and when given properly are almost free of all hazard.

Heat may be applied locally to the articular or periarticular diseases, neuritis, myositis, muscle spasm, and contractures. General body exposure to heat may be given in multiple arthritis, renal disease for elimination, neuroses, and many of the cerebrospinal cord diseases, especially those involving the pyramidal tracts. Heat should always precede massage and therapeutic exercise, as its application with relaxation, and increased blood supply will enhance their effect and increase the tolerance of the patient. Careful consideration must be given to those patients with sensory disturbances. The mode of heat application is extremely varied, and one makes his preference according to the best results he can obtain.

Hydrotherapy continues to be the favorite with many, regardless of the great

advance in the electrical apparatus, such as dry-air heaters, light cabinets, diathermia, and radiotherapy. Tepid baths of 85° to 95° F. are useful in neuroses, myocarditis, nephritis, spastic or flaccid paralysis, paraplegias, with or without impairment of the sphincters, cerebrospinal cord tumors, multiple sclerosis, dystonias, and myotonias. It often gives results in the chronic cardiovascular diseases that are not too severely decompensated and may be administered with carbon dioxide or the simple modified Nauheim bath.

Massage is an important adjunct to other therapeutic measures in the diseases heretofore mentioned, but applied lightly for its sedative relaxation, firmly and deeply for stimulation.

Hot baths of 95° to 110° F. are indicated in chronic inflammation of the bones, joints and muscles, and are particularly well tolerated by, and greatly benefit, those patients with chronic multiple arthritis, both the proliferative and degenerative types. It not only permits greater mobility of the affected joints with less discomfort, but serves to minimize the development of contractures. For the same reasons and in addition for the relief of pain and crises, it may be administered often with gratifying results in manifestations resulting from cerebrospinal syphilis.

This treatment has the advantage in that it may easily be given daily and readily administered alike at home or in the institution.

The hydromassage by whirlpool bath is a simple method of local treatment to the upper or lower extremities for peripheral neuritis, extensive ulcerations, arthritis, vasomotor and sensory changes in spinal cord diseases, stumps in postoperative amputation, in some cases of peripheral vascular diseases, and in gangrenous and suppurating wounds of extremities.

Hot sitz baths are also given for sedative effect in conditions involving the genitals, lower pelvis, and rectum, including cystitis, urethritis, and prostatitis.

The deep-radiant lamp, 250 to 500 watts, for local use, and 1,500 watts for the more general application, also the heaters with luminous lamps, are the most convenient to use and are applicable in practically all conditions heretofore mentioned. Because of their sedation on nerve endings and their deeper penetration of superficial tissues, the radiant lamp is more generally used for local treatment for 15 to 45

minutes, or as in the condition of peripheral vascular diseases, a low degree of heat continuously. Entire-body exposure may be made in light cabinets with carbon filament lamps for diseases necessitating elimination, such as removal of urea, toxins, and metallic poisons as lead, arsenic, and mercury—or with tungsten filaments for their neurovascular effects.

The advent of the use of diathermia in physical therapy presents an effective agent for the application of heat to the very deep structures. It has added to our facilities and increased beneficial results in our treatment of chronic diseases.

Because it increases blood and lymph supply to the part and dilatation of the vessels, its sedative action on sensory and motor nerves, it produces relaxation, increased nutrition, and absorption of exudates. Locally it is efficacious wherever heat is indicated, as in arthritides, articular and periarticular, spinal cord diseases, neuritis and neuralgias, angina pectoris and coronary disease, ununited fractures, fibrous ankylosis, peripheral vascular diseases, synovitis, and myositis. In the form of autocondensation, it is palliative in all types of hypertension and may be the means of averting many cases of cerebral apoplexy. Excessive heat is not well tolerated in cardiac and pulmonary diseases and aged; also in peripheral vascular diseases, vasomotor and sensory paralysis, hypertension, aneurism and functional neurosis.

In massage, Ralph Pemberton⁶ states that it usually has its chief application in respect to the various chronic conditions and diseases, and that its therapeutic effect is achieved slowly and repeatedly over a long period of time. It is given to maintain, improve, and correct errors in physiological functions in the soft tissues.

Besides its sedative effect on spastic muscles, it causes relaxation to these contracted tissues as well, and it may prevent or overcome impending contractures in many diseases of the cerebrospinal cord, peripheral nerves, and joints.

For sedative effect, to reduce spasm, the light form of effleurage is necessary, but the deeper and stronger petrissage is essential in arthritis and beginning contractures. In edema from renal and cardiac disease and vasomotor disturbances, it is an important adjuvant therapy. Effleurage and petrissage are both applied to empty the superficial and deeper tissues.

As many of the chronically ill patients are confined to a sedentary existence, massage is the substitute for the activity to which they at one time have been accustomed. One of the purposes of massage is to prepare these patients for therapeutic exercises. Massage is to be avoided in phlebitis and thrombosis, chronic ulcerative colitis, purulent infections (osteomyelitis).

Exercises are usually first given in conjunction with thermotherapy and massage in the form of passive, assistive and resistive movements, and finally the active exercises which are so essential for some degree of restitution. The early movements are performed by and with the attendant who should have a thorough knowledge of the movements of each joint. This will prepare the muscles for future voluntary activity, increase mobility, prevent contractures, and counteract deformities.

Burbank suggests small amounts of exercise, either active or passive, frequently taken, to be more beneficial than any large amount at one time. Moderation of massage and exercise and physical therapy (heat) is advisable, as trauma is to be avoided. Should the joints become more painful one half to one hour after the exercise is concluded, there has been traumatization, and the amount should be decreased until such increase of discomfort no longer follows exercise or massage. Most of the chronic cases have a low metabolic rate (unlike the acute, which have an increased metabolic rate). This may be increased by massage and exercise.

These exercises may be first given in bed and the early active exercises to the upper extremities given to these patients in the wheel chair. Following this, the patient may be supported on walking chair or crutches and begin the rudimentary action of standing and walking. The necessity of proper instructions in standing and walking is essential, as they will tend to make any form of movement though ungainly, that will require the least effort in propulsion. In institutions with mechanotherapy equipment, there is the advantage in having a class of patients performing exercises which keep their incentive and interest maintained.

Reeducation of muscles for physical exercises is necessary for developing neuromuscular coordination. Jones⁸ postulates that weak muscles (usually much relaxed) are never restored when under continuous strain, as in wrist or foot drop. It is there-

fore important that the weak muscles are put to work or exercise with relaxation to the antagonistic contracted muscles. Muscular reeducation entails proper instruction by the attendant and consistent practice by the patient.

Prolonged exercises are to be avoided, as patients with chronic diseases are readily exhausted with a tendency to nervousness and excitement. Strenuous exercises are also to be guarded against in overstretched muscles.

CORRELATION OF MEDICAL SURGERY AND PHYSICAL THERAPY TREATMENTS—In writing his work on physical therapy regarding pathological conditions Granger⁶ stresses the importance of keeping in mind that all physical measures are only a part of the triad—medicine, surgery and physical therapy. In the main, physical therapy is used as an adjunct to ensure functional restoration. It should only be prescribed after a careful examination has been made both physical and laboratory, and all etiological factors sought, and if found eliminated. Proper medical and surgical procedures should go hand in hand with physical therapy treatment. It is only by combination of methods that success is obtained.

In many conditions, physical therapy should be preceded by such surgical or manipulative measures as will put the parts in correct position for function. Orthopedic conditions after operation would often be void of satisfactory results if followed by inadequate physical therapy.

Only too often patients have been referred that appeared hopeless for therapy, many who had a variable number of diseases or disabilities but continuous effort, had wrought a better and happier individual.

Sampson⁹ states this clearly, in that a very heavy responsibility rests upon the shoulder of any medical man who assumes to condemn physical therapy remedies without proper trial or without the most painstaking and careful study.

Not only is he denying his patients any benefit that might accrue from an intelligent use of these remedies under trained medical supervision, and by his example causing numerous other medical men, who look to him for guidance, to do the same thing, but he is handing over to the irregulars (cults and charlatans) the most valuable section of the therapy field and

practically forcing all patients who need and desire physical treatment to resort to these forces to obtain it.

These patients are intelligent enough to prefer receiving physical treatment from medical men, but where this is not possible, they have no hesitancy in seeking it elsewhere.

GUN HILL ROAD, NEAR JEROME AVE.

THIS AND THAT

The universal tendency to make the long-suffering doctor the "goat" is illustrated again by a correspondent of the *New York Times*. As he relates, a proposition to use CWA funds to pay doctors to examine school children for a defect found among them in alarming proportions was considered favorably, and the ground-work was laid for its completion. Suddenly there was a cessation of activity. Someone had learned his lesson in municipal economies. The doctor never complains: then why pay him for such work?

The result is that school children are being sent by teachers and social workers to the clinics in ever-increasing numbers to be examined for this defect. The doctor again is left playing the goat!

A western medical paper tells of a mother who gave her daughter a book telling "What Every Young Girl Should Know," and daughter wrote to the author suggesting a couple of dozen corrections and the addition of two new chapters.

General practitioners in some parts of the country, according to a speaker at a medical meeting in Milwaukee, are making a strong appeal to those in special fields of surgery to have a standard of fees adopted which would make it possible for the general man to collect for his services. These services include not only his diagnosis and valuable advice for surgery, but also transportation of the patient, after-care, and all services except those which go on in the operating room. Were such a standard adopted the general man would no longer be considered a mere on-looker in the case, for the patient would never lose sight of the importance of his position. Such a standardization would tend to do away with the evils of fee-splitting.

The ideals of Osler are presented in a quotation in the *Canadian Medical Association Journal*, as follows:

"I have had three personal ideals. One to do the day's work well and not to bother about tomorrow. It has been urged that this is not a satisfactory ideal. It is; and there is not one which the student can carry with him into practice with greater effort. To it, more than anything else, I owe whatever success I have had

—to this power of settling down to the day's work and trying to do it to the best of one's ability and letting the future take care of itself. The second ideal has been to act the Golden Rule as far as in me lay, toward my professional brethren and toward the patients committed to my care. And the third has been to cultivate such a measure of equanimity as would enable me to bear success with humility, the affection of my friends without price, and to be ready when the day of sorrow and grief came to meet it with courage befitting a man."

Fewer accidental deaths of children in the home and on the streets are noted by the Metropolitan Life Insurance Company, which credits this encouraging fact to the teachings of the safety education campaigns conducted in the schools. In the past nine years the death rate among boys and girls under 15 years from home accidents has declined nearly 23 per cent. But among the older persons, from age 15 onward, the death rate from home accidents rose nearly 42 per cent from 1923 to 1932, and in the latter year it was the highest on record. Is the home, then, a more hazardous place for grown-ups than for children? Not necessarily. The increased number of adults, we are told, killed in domestic accidents may be a reflection of the business slump which has forced large numbers of persons to remain at home, who, in normal times, would be employed elsewhere during a large part of the day.

The theory that evolution is on the back track, and that man is on his way to being a monkey again, has been supported hitherto mainly by the monkeyshines of certain persons who wish to be prominent in the public eye. Now word comes from London that a baby has been born in the Metropolitan Hospital with a tail. It is "about two inches long, tapers to the point, and is curly and normally sensitive." The tail is growing, and, on the whole, doing as well as could be expected. Of course, there may be others about that have been kept under cover and not reported, and might prove useful in hanging from a window in case of fire, or come in handy in many ways. Further evidences of evolutionary reversal should be watched for with special care from now on.

A STUDY OF SECONDARY CASES OF SCARLET FEVER

WILLIAM H. BEST, M.D.

Director, Bureau of Preventable Diseases, Department of Health, New York, N. Y.

A previous study of 11,357 cases of scarlet fever occurring in the City of New York during 1931, a year in which the incidence of scarlet fever was approximately normal, revealed that about 8 per cent of the cases were secondary cases, with 2.4 per cent of the 37,788 contacts developing scarlet fever. An analysis of the data gave the impression that the majority of uncomplicated cases are very slightly, if at all, infective after the 21st day, only 4 per cent of the secondary cases having developed subsequent to the 21st day after the onset of the primary case. In the complicated cases, however, the secondary cases arising after the 21st day were materially higher, 18 per cent of the secondary cases to complicated scarlet fever developing later than the 21st day.*

As a result of this study, the conclusion was drawn that scarlet fever cases after a careful examination to rule out the presence of a complication (discharging ear, mastoid, nose, enlarged glands) could be terminated on the 21st day, irrespective of desquamation, with little or no danger of causing secondary cases.

Accordingly, the Borough of Brooklyn was chosen as a test, and regulations were drawn up permitting termination and discharge of all uncomplicated scarlet fever cases on the 21st day. These regulations went into effect July 1st, 1932. The remaining four boroughs of the city continued to hold uncomplicated cases until the 30th day, in accordance with the regulations already in force. The termination of complicated cases remained the same throughout the city, that is, until the complication had cleared up.

The present study is an analysis of the data after sufficient time has elapsed to determine whether the conclusions arrived at previously could be substantiated.

In Brooklyn, from July 1st, 1932, to October 31st, 1933, a period of 16 months, there were 2,602 primary uncomplicated cases, which gave rise to 243 secondary cases, or 8.5 per cent secondary cases. In the control boroughs, there were 5,810 primary uncomplicated cases, and 598

secondary cases, or 9.3 per cent secondary cases. The secondary cases in this study were slightly higher than in the previous study, in which the percentage was 7.8.

In Brooklyn, to the 2,602 primary cases, there were 9,410 susceptibles, and of these 9,410 susceptibles, 243, or 2.6 per cent, developed the disease. In the control boroughs, to the 5,810 cases there were 22,105 susceptibles, and of these 598, or 2.7 per cent, developed the disease. It is interesting to note that the percentage of susceptible contacts later coming down with scarlet fever was but very slightly higher than in the 1931 study (in which it was 2.4 per cent), and that the Borough of Brooklyn made a better showing than the control boroughs.

While the percentage of primary cases causing secondary cases and the percentage of susceptible contacts developing secondary cases gives a very satisfactory showing for Brooklyn compared with the control boroughs, if a study is made of the time intervals in which the secondary cases developed after the onset of the primary case, another phase of the subject presents itself. For this purpose, a tabulation was made at 5 day intervals showing the number of secondary cases arising in each period during the primary case.

It will be seen from Table III that the number of secondary cases developing in Brooklyn in the 27- to 30-day period, and in the 31- to 37 day period was higher than in the control boroughs and also higher than in the previous study. The cases that developed in the 27- to 30 day period were probably infected (allowing for the incubation period) between the 22nd and 26th days, while the secondary cases that developed in the 31- to 37-day period were probably infected between the 27th and 30th days. Therefore, with 7.3 per cent of the secondary cases developing in Brooklyn as against 4.1 per cent in the control boroughs between the 27th and 37th days, it would seem that the difference, or 3.2 per cent, might be charged to the release of the primary cases on the 21st day. The conclusion to be drawn from this is that there may be a certain small percentage of

* *N. Y. State Jour. Med.*, Vol. 33, No. 14

scarlet fever cases still infective after the 21st day.

In order to translate this 3.2 per cent increase between the 27- to 37-day period in Brooklyn over the control boroughs into actual cases, it would mean that 7.5 secondary cases developed as a result of the 21-day isolation period.* Therefore, by releasing 2,602 primary uncomplicated cases in the Borough of Brooklyn on the

the secondary cases that might develop through contact outside the immediate family. If, however, there were a marked increase in extra-household secondary cases due to the 21-day isolation period, this should manifest itself in an increase in the attack rate in the school population of Brooklyn, as compared with that of the control boroughs. This we do not find.

Comparing the attack rates (Table IV)

Total	850		243		598	

21st day, 7.5 more cases developed than if isolation had been maintained for the 30-day period, or, for every 1,000 primary uncomplicated cases of scarlet fever there would be an increase of approximately 3 cases (2.88 to be exact). Our 10-year average of scarlet fever from 1923 to 1932, inclusive, was 11,090, of which approximately 92 per cent were primary cases, and on this basis with a 21-day isolation period established for the entire city we might expect 29 additional cases annually.

Upon release from isolation the majority of scarlet fever cases return to school and come in contact with susceptibles outside of the household. Our statistics are, of course, based on secondary cases arising in the immediate household, as there is no way of determining with any exactness

TABLE IV

	School pop. 5 to 14	Cases 5 to 14	Attack rate per 1,000 pop.
1931			
Brooklyn	422,397	2250	5.33
Manhattan	229,978	1488	6.47
Bronx	193,819	2398	14.95
Queens	163,048	1372	8.41
Richmond	27,722	147	5.30
City	1,036,964	8155	7.86
July 1, 1932 to Oct. 31, 1933			
Brooklyn	418,774	1935	4.62
Manhattan	221,274	1159	5.24
Bronx	192,238	1171	6.09
Queens	166,983	1126	6.74
Richmond	27,843	252	9.05
City	1,027,112	5643	5.49

of the various boroughs for the periods of both studies, it is noted that the attack rate in Brooklyn was as low or lower than any of the boroughs during the period of the two studies. It is interesting to note that while Bronx had a high attack rate during the period of the first study, the

* 243 secondary cases is 3.2 per cent more than we should have had, hence 243 equals 103.2 per cent, or 235.5 cases, which, we assume, would have been the number of secondary cases with a 30-day isolation period.

attack rate was about average during the second study, and while the attack rate in Richmond was the lowest during the period of the first study, it was the highest during the period of the second study. This is consistent with the variation in susceptibility in a community from year to year, and hence it might be expected that with an attack rate (5.33) considerably below the average (7.86) in Brooklyn during the period of the first study, we might normally expect an increase above the average in the attack rate in Brooklyn for the period of the second study. However, we find the reverse is true, that is, in Brooklyn with a 21 day isolation for the 16 month period, the attack rate is lower than in the same borough with a 30 day isolation period for the 12 months of 1931, and also lower than the other boroughs with a 30 day isolation period.

If the release of cases of scarlet fever on the 21st day and the resumption of their normal activities caused an appreciable number of additional cases in this most susceptible age group, it should show in the attack rates, hence, it would seem that with the lowest attack rate in Brooklyn during the period of 21-day isolation, there was not enough contagium present after the 21st day to cause sufficient additional cases to increase the attack rate above that with a 30 day isolation period.

SUMMARY

(1) There was a lower percentage of secondary cases of scarlet fever with a 21-day isolation period than with a 30 day isolation period.

(2) Approximately the same percentage of susceptible contacts developed the disease in the 21-day isolation group as in the 30 day isolation group.

(3) There was an increase in the ratio of secondary cases developing after the 21st day to the total number of secondary cases in comparing the 21 day isolation with the 30 day isolation group. This increase would amount to approximately three cases for every 1,000 cases.

(4) The attack rates for the various boroughs for 1931 and for the period of the present study do not show that any appreciable increase resulted from a 21-day isolation period.

(5) Three additional scarlet fever cases per 1,000 do not seem to warrant an additional 9,000 days' isolation—the difference in isolation time per 1,000 cases between a 21-day and a 30 day isolation period—or in an average year, 90,000 days additional isolation.

1198 BUSHWICK AVE., B'KLYN

Philadelphia Academy of Surgery THE SAMUEL D GROSS PRIZE FIFTEEN HUNDRED DOLLARS

ESSAYS WILL BE RECEIVED IN COMPETITION FOR
THE PRIZE UNTIL JANUARY 1, 1935

The conditions annexed by the testator are that the prize shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo in length illustrative of some subject in Surgical Pathology or Surgical Practice founded upon original investigations, the candidates for the prize to be American citizens.

It is expressly stipulated that the competitor who receives the prize shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D Gross Library of the Philadelphia Academy of Surgery, and that on the title page it shall be stated that the essay was awarded the Samuel D Gross Prize of the Philadelphia Academy of Surgery.

The essays, which must be written by a single author in the English language should be sent to the Trustees of the Samuel D Gross Prize of the Philadelphia Academy of Surgery, care of

the College of Physicians, 19 S 22d St., Philadelphia, on or before January 1, 1935.

Each essay must be typewritten distinguished by a motto and accompanied by a sealed envelope bearing the same motto, containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay.

The Committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents within one year.

The Committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

HYPERTENSION AND NEPHRITIS

MAYNARD E. HOLMES, M.D., F.A.C.P.

From the Medical Department, University Hospital, Syracuse University Medical College, Syracuse, N. Y.

Because of the considerable change in recent years of our understanding of nephritis and hypertension, this discussion will consider the recent developments particularly where they have radically changed our former views on both diagnosis and treatment.

Minimal nephritis is relatively common, being present in most individuals over forty years of age. It may also accompany many conditions, such as acute and chronic infections, arteriosclerosis, heart disease, and certain poisonings. This damage, however, is usually not of a degree to cause impairment of kidney function, and because of lack of symptoms it is often overlooked. Chronic Bright's disease frequently accompanies some other condition which is the chief cause of symptoms and finally is the cause of death; hence, as a primary diagnosis it is surprisingly uncommon. At the Syracuse University Hospital a review of 699 cases from the Medical Department revealed only 4 instances of chronic nephritis as a primary diagnosis, while pernicious anemia, for example, occurred in 12 cases. Well-established Bright's disease is often overlooked, especially those types which do not show albuminuria or edema. It is also a frequent error to diagnose nephritis when it is either absent or of a degree insufficient to cause symptoms or death. These errors are due in great part to the common impression that the diagnosis of Bright's disease is largely dependent on the presence or absence of albuminuria, edema, or hypertension. These symptoms may be present in individuals with normal kidney function, and conversely they may be absent at times when a severe grade of nephritis exists.

While *albuminuria* is usually present at some stage in all cases of Bright's disease, it is not of itself diagnostic of nephritis. The error is often made of accepting all albumin and sediment present in the urine as coming from the kidneys. They may be due to blood, pus, or mucus from sources other than renal. This error can be overcome by examining fresh catheterized specimens especially in women. Congestive heart failure is often accompanied by

marked albuminuria and probably explains the term *cardiorenal disease*. It usually clears with the return of compensation. A decompensated heart is at times overlooked and neglected, because the albuminuria and edema present are regarded as being due to nephritis. Benign albuminuria occurs rather commonly, in 6 to 30 per cent of healthy children¹ and in 5 per cent of robust young men.² In children it is often of the so-called *orthostatic type*. On the other hand persistent albuminuria in young adults may be due to a latent or quiescent phase of *chronic Bright's disease*. The presence of albuminuria should always be an indication to make a careful study of the urinary sediment and to carry out the various kidney function tests before deciding whether or not nephritis is present.

Edema is commonly looked upon as the sign par excellence of Bright's disease, yet it is much more commonly caused by *circulatory failure*. Edema is also present at times in the anemias, myxedema and in certain nutritional disturbances. The edema that occurs late in the dry type of chronic nephritis is often due to the development of *cardiac failure*. True renal edema is usually associated with severe albuminuria which has brought about a marked lowering of the serum albumin. Recent experimental work^{3, 4} indicates that renal edema is closely related to this depletion of the serum albumin. It has been demonstrated that if the plasma protein is lowered to a figure below 4 per cent, or the serum albumin to below 1 per cent, then edema will make its appearance and will clear when they are restored to their normal level. The relationship of the plasma colloid osmotic pressure to edema has recently been reported.⁵⁰

The microscopic examination of the urine and certain kidney function tests yield the most dependable evidence regarding the presence or absence of Bright's disease. Considerable error often enters into the microscopic study of the urinary sediment because of lack of care in obtaining the specimen. Addis⁵ has stressed the point, that casts and red blood cells quickly

disappear from urine that is alkaline or of low specific gravity, or that is not fresh. He advises the examination of a *fresh* specimen obtained after twelve hours of a dry diet and the withholding of fluids to insure both acidity and concentration. The common practice in both office and hospital of examining urine specimens several hours after collection is open to error and should be corrected. The presence or absence of red blood cells and the type of casts present are important. It must always be kept in mind that an occasional hyaline cast and red or white blood cell may be present in normal urine⁶ and that they may be increased during congestive heart failure.⁷ The type of cast present is an indication of the degree of pathologic activity in the kidney; the coarsely granular cast indicates considerable activity, next comes the finely granular, and then the hyaline cast indicating the least activity. Addis has called attention to the wide brown casts seen in the terminal stages of nephritis.⁸

The important methods for the measurement of renal function are the concentration and dilution or Mosenthal test, the phenolsulphonaphthalein dye test and the estimation of urea or the total nonprotein nitrogen in the blood. The concentration and dilution test is probably the most sensitive. It reveals early signs of diminished renal function by an increase in the night urine and by gradual failure to concentrate. The dye test is next in sensitiveness; and the commonly used estimation of the blood urea or nonprotein nitrogen is the least sensitive, usually showing an increase only after the dye excretion has dropped to a very low level.⁹ The concentration test which is the most valuable can be easily carried out in the office or home with no special equipment other than a graduate and urinometer. The urea clearance test¹⁰ is considered by some to be the most sensitive and reliable measurement of kidney function. However, as yet it has not come into general use and further trials will be necessary to establish its true value. During congestive heart failure all the renal function tests may give false abnormal findings and they should be repeated when compensation has been attained. Another test of value in diagnosis and particularly in treatment is the estimation of the plasma protein. Marked decrease is noted in nephrosis and the nephrotic types of

chronic nephritis. It should be emphasized as in any laboratory procedure that tests giving abnormal findings should always be repeated one or more times before accepting the evidence as significant.

Diminished output of urine under certain conditions, such as acute infections and after surgery, is often looked upon as evidence of impaired kidney function. If albuminuria and edema are absent it is much more likely to be due to inadequate intake or abnormal loss or storage of water. It is not generally appreciated the large amount of water that may be lost each day through the skin and lungs. Because of the fact that probably 60 per cent of the water intake each day comes from food, it is easy to see that under conditions where solid food is cut off, the water intake may become inadequate and little or no urine be excreted. DuBois¹¹ has called attention to this situation and points out the necessity of proportionally increasing the fluid intake under these conditions so that the water intake will be at a level necessary for normal body functions. It should also be kept in mind that little or no urine will be excreted during periods of circulatory collapse despite normal kidneys. Diminished excretion of urine in the absence of albuminuria is likely to be of extrarenal origin if the concentrating power of the kidney is found to be unimpaired.

There are numerous classifications of Bright's disease most of which are on an anatomic basis although some are founded on clinical and laboratory evidence. The many classifications of nephritis are a source of considerable confusion to many students and practitioners especially the correlation of one classification with another. Also it is often puzzling to have the necropsy findings fail to confirm the anatomic changes suspected from the clinical course during life. This in part is due to the fact that the kidney ultimately found at autopsy reveals the terminal stage of the disease when the damage is not confined to any one component but involves not only the glomeruli but also the tubules, interstitial tissue and the blood vessels. The most simple classification of nephritis would be to limit it to the acute and chronic variety. However, it is of interest and of help in prognosis and treatment to subdivide the chronic form. The oldest classification in use at the present time is

that which divides chronic nephritis into the parenchymatous and the interstitial types. In 1914, Volhard and Fahr¹² presented their classification which divides chronic Bright's disease into the degenerative or nephrotic, the inflammatory or glomerular, and the arteriosclerotic or hypertensive. Christian¹³ on a clinical basis in 1925 divided chronic nephritis into that form with edema, and that form without edema. This classification is relatively easy to apply because it is based on signs and symptoms present during life. The most recent classification of Bright's disease is that of Addis⁵ which is based upon the findings in the urinary sediment. With a special technique the number of casts, red and white blood cells are estimated for a 12-hour period and according to the findings the case is grouped as one of hemorrhagic, degenerative, or arteriosclerotic Bright's disease. He believes that the hemorrhagic form has its beginning with some cute infection notably tonsillitis and gradually evolves through the initial, latent, active and finally the terminal stage.

It is obvious that certain terms in each of these different classifications must represent the same or a similar clinical and pathologic picture. Therefore, for purposes of correlation and simplicity the terms parenchymatous nephritis, glomerulonephritis, diffuse nephritis, nephrosis, hemorrhagic and degenerative Bright's disease, and chronic nephritis with edema may be said to represent the same variety of nephropathy. This type is more often seen in the young age group; it may occur in an acute, subacute, or chronic form. The pathologic lesion is an inflammatory and degenerative process in the glomeruli and tubules. Albuminuria and edema are striking features. The urinary sediment reveals many casts and many red and white blood cells. Hypertension and abnormal response to the renal function tests do not occur until late, when considerable contraction of the kidney may develop. When the disease is recognized these patients usually live but a few years.

In like manner the terms interstitial nephritis, hypertensive or arteriosclerotic nephritis, nephrosclerosis, arteriosclerotic Bright's disease, and chronic nephritis without edema may be looked upon as synonymous. They designate a type of Bright's disease occurring more commonly after forty years of age, usually chronic in

form and extending often over a period of many years. The primary anatomic change is in the arterioles, interfering with the nutrition of the glomeruli and tubules and ultimately leading to destruction of these units. Hypertension and nocturia are prominent characteristics, and no edema is present until late when it may appear on a cardiac basis. There is usually little or no albuminuria and the urinary sediment reveals almost no casts or red blood cells. There is evidence of impaired kidney function as gauged by the response to the various renal function tests. If all patients suffering from hypertension and generalized vascular disease are placed in this group as they commonly are, then in only about 10 per cent is there serious impairment of kidney function or death from uremia; the renal damage is minimal and vascular changes in the heart and brain progress at a more rapid rate causing death long before kidney insufficiency sets in. Because of these important facts it would be much more satisfactory, particularly in prognosis and treatment, to place this large group with minimal renal damage under some other term such as vascular or essential hypertension and designate as having nephritis only those cases exhibiting definite impairment of kidney function.

Nephrosis is a rare form of nephropathy, occurring in children and young adults; it is considered by many not to be a true nephritis. It is characterized by marked albuminuria and massive edema which seems to disappear and reappear without any apparent reason. There is normal response to all kidney function tests, doubly refractile lipoid bodies appear in the urine, the blood cholesterol is elevated, and at times the basal metabolism is lowered. There is no tendency to hypertension or retinal changes, and no red blood cells appear in the urine. There is pronounced lowering of the plasma protein and serum albumin due to the marked loss of albumin in the urine. The important pathologic finding is an extensive degenerative change in the tubular epithelium. Few cases ever completely recover.

The *eyegrounds* of patients who have hypertension or nephritis reveal certain changes which are of great help in diagnosis, prognosis and in treatment. These findings in the retina are now looked upon as being due primarily to hypertension and

vascular changes rather than to pathology in the kidney.¹⁴ These eyeground findings may be divided into two groups, the benign or arteriosclerotic, and the malignant or neuroretinitis. The arteriosclerotic form consists of irregular, tortuous, narrowed vessels, with compression of the veins at arterial crossings, also hemorrhages and hard white spots. This is the common and benign form; only about one-third¹⁴ of this group exhibit any impairment of renal function. Its presence is not so much an evidence of nephritis as of generalized vascular disease, particularly in the brain.¹⁵ Death usually results from cardiac or cerebral vascular disease. The malignant or neuroretinitis form is characterized chiefly by edema of the disk and retina with the stellate figure at the macula, the snow-bank exudate and the cotton-wool patches. This type is not so common and is of much more serious importance, 90 per cent dying within two years, and 70 per cent having serious impairment of kidney function.¹⁴ Patients who exhibit this form of retinopathy are said to have malignant hypertension. The commonly used term "albuminuric retinitis" is inappropriate and misleading and is being discarded rightly. It has no relation to albuminuria. It is often present when albuminuria is absent, and it is usually lacking when severe albuminuria exists.

Hypertension is commonly looked upon as an indication of Bright's disease while, as a matter of fact, only a small percentage of individuals with high blood pressure ever show any significant impairment of renal function. In the past, too much stress has been placed on the kidney as a cause of hypertension. The renal lesion is more likely a result rather than a cause of the high blood pressure. The method of making blood pressure estimations is important. Because of the transitory elevation of blood pressure due to increased nerve tension one must be cautious in accepting the first reading made as an indication of the patient's usual blood pressure. Many patients are labeled as having hypertension because of failure to appreciate the effect of nervousness on vasomotor tonus. To overcome this error an effort should be made to obtain a complete relaxation of the patient, and at least three readings should be taken. Often when the first reading is substantially elevated the third will be within normal limits. The old rule that

the normal blood pressure is 100 plus the age has been discarded. Symonds¹⁶ in a large series of normal individuals found that for all ages the average systolic pressure does not exceed 135 and the diastolic 90 mm. of mercury. A persistently high diastolic pressure is looked upon as much more serious than a high systolic pressure. Despite an enormous amount of investigation the etiology of hypertension except for the 10 per cent on a renal basis, is at present unknown. The earliest sign noted in the development of hypertension is a tendency for the blood pressure to fluctuate above normal, due apparently to a transient increase in vasomotor tonus. Later this temporary elevation becomes permanent and the pressure remains fixed at a level above normal; sclerotic changes gradually appear in the arterioles throughout the body. This arteriolar change after a time seems to become more extensive or to focus in certain organs such as the heart, brain, or kidney. Finally, failure of one of these vital organs occurs and the patient dies of heart disease, apoplexy, or uremia. In some instances the vascular process will not be general but will be found to be sharply localized to one organ or structure. The vast majority of individuals with hypertension never develop impairment of kidney function and only 4 to 10 per cent die of renal failure. This fact is not as generally appreciated as its significance warrants and the former conception of the renal origin of hypertension still influences both diagnosis and treatment. Bell and Clawson's¹⁷ report of 420 patients with hypertension, revealed death due to heart failure in 45 per cent, coronary involvement in 16 per cent, apoplexy in 20 per cent, renal failure in 8 per cent, and other causes in 12 per cent. Christian's¹⁸ series of 131 cases shows death to be due to cardiac failure in 32 per cent, cerebral accident in 25 per cent and uremia or severe renal disease in 4.5 per cent. In a series of 100 cases of hypertension coming to autopsy Scott¹⁶ found as the cause of death myocardial failure in 68 per cent, cerebral accident in 22 per cent, and renal failure in 10 per cent.

In the treatment of Bright's disease one should first consider what particular functions of the kidney are impaired and then devise a plan of therapy that will put as little call as possible upon them. The renal

function tests will indicate the manner in which kidney activity is impaired whether it be in the excretion of salt, water, or protein metabolites. As drugs are unfortunately of little help, treatment resolves itself into the maintenance of proper nutrition guarding against deficiencies in calories, protein, minerals, and vitamins. This is important because it has been shown that undernutrition increases the severity of the renal lesion.²⁰ Failure to maintain proper nutrition is a common error in the treatment of nephritis and this is most strikingly exemplified in the management of the protein intake. The presence of nephritis, hypertension, albuminuria or edema is commonly looked upon as an indication to withhold the much maligned meats and other protein foods. This régime is often followed by the development of lack of endurance, anemia, and other evidences of disturbed nutrition due to protein starvation. These symptoms are often looked upon as being due to the disease but they quickly clear upon the return to a normal well-balanced diet. The fact that there is certain minimal amount of protein necessary each day to prevent depletion of the body store of protein is completely lost sight of. It is usually considered that the minimum amount of protein on which a person can remain in nitrogen equilibrium is about 0.5 to 0.7 gm. per kilo,²¹ and no patient should be restricted below this figure except for a brief period. McCann and Keutmann²² gave patients with active hemorrhagic Bright's disease diets containing 75 to 200 gm. of protein a day without adverse effects. The important indications for restriction of protein are not albuminuria, high blood pressure, or edema, but definite evidence of difficulty in excreting protein metabolites, as shown by the elevation of the blood urea or nonprotein nitrogen and failure of the kidney to concentrate to at least 1020. When these criteria are lacking a normal protein intake should be allowed and when restriction is indicated it should not be below the minimal figure. The old idea that red meats were more harmful than white meats and that animal protein was more harmful than vegetable protein has been discarded; all proteins are the same to the kidney. When considerable albumin is lost in the urine each day and the plasma protein is lowered to below 4 per cent a protein intake of 150 to 200 gm. may be necessary. High protein diets are not permissi-

ble if there is inability to concentrate or an increase in the blood urea or nonprotein nitrogen is present. Hence it becomes evident that in some cases of Bright's disease a normal protein intake should be allowed; in others it should be restricted, and in still others it should be increased. In chronic nephritis without edema the normal daily intake of fluids must be increased because the kidneys can only eliminate solids in a very dilute solution. Hence, considerable water is needed to perform their work, and for similar reasons these patients should not be treated with hot packs as is commonly the case especially in uremia. Diuretics have no place in the treatment of nephritis, except when edema is present, and here the acid types of diuretics²³ are often efficacious, together with the limitation of the intake of salt and water. An effective method at times of initiating the excretion of urine in patients with anuria due to nephritis is the intravenous administration of a 20 to 30 per cent glucose solution. Patients with acute nephritis should be thoroughly investigated for foci of infection particularly in the tonsils. If these foci are found they should be eradicated but only after the acute process has subsided. In the treatment of the albuminurias incident to pregnancy and acute infections there is no justification for the restriction of the protein intake unless impaired renal function can be demonstrated. The convulsion and other nonuremic cerebral manifestations of glomerulonephritis and hypertension can best be treated by lumbar puncture to relieve the increased intracranial pressure and by depleting the cerebral edema with hypertonic solutions, particularly magnesium sulphate.²⁴

The treatment of patients with hypertension is often severe, harmful and to no point. Protein restriction is commonly prescribed without the slightest evidence of impaired kidney function. All that has been said here regarding the protein intake in nephritis applies to hypertension, and with greater emphasis because only a very small percentage of these individuals have more than a slight impairment of renal function. The mismanagement of the protein intake is no doubt due to the older views that nephritis was the cause of high blood pressure and that protein should be restricted in all forms of Bright's disease. Except for those few cases having impairment of kidney function, a protein intake of about 1 gm. per kilogram should be al-

lowed. Newburgh^{25, 26} has reported the production of nephritis and vascular changes in animals fed a high protein diet, but the doses of protein were in proportion far in excess of the normal protein intake in man. Severe restriction of salt as advocated by Allen has been discarded,²⁷ likewise all specific drug therapy the latest of which has been potassium sulphocyanate²⁸ and bismuth subnitrate.²⁹ The marked lability of blood pressure makes it very difficult to appraise the effect of any treatment upon it and has often lead to overenthusiastic claims for many remedies. Overweight should be corrected and these patients must always be watched for the development of serious cardiac or cerebral vascular disease. Perhaps the most striking feature of the hypertensive patient is the nervous instability present. He is usually of the high-strung, emotional, and worrisome type. To correct this condition is perhaps the most important factor in treatment and yet the most difficult to attain. It involves not only all the daily activities of the home and business life but also the much more difficult problem of overcoming certain inherited qualities and defects. Frequent changes and vacations are of great value but only if the patient can afford them. Treatment then resolves itself into the relief of all stress, particularly mental stress, and moderation in all habits and activities.

SUMMARY

1. While commonly present at some stage in most cases of Bright's disease, albuminuria, edema, and hypertension are not of themselves diagnostic of impaired kidney function.

2. The most dependable evidence regarding the presence or absence of nephritis is to be obtained from the microscopic examination of the urinary sediment and from the various renal function tests.

3. A plan has been suggested for correlating and simplifying the various classifications of nephritis.

4. The vast majority of patients with hypertension exhibit no serious impairment of kidney function and only 4 to 10 per cent die of renal insufficiency. Death is usually due to vascular cardiac or cerebral complications.

5. All cases of hypertension should be classified under some such term as vascular or essential hypertension until the clinical course justifies a diagnosis indicating defi-

nite involvement of the heart, brain or kidneys, instead of the common practice of grouping all of these cases under the term nephritis.

6. There is no justification and there may be actual harm in the restriction of meats and other protein foods in the presence of nephritis, albuminuria, edema, or hypertension unless impaired kidney function can be demonstrated.

function tests will indicate the manner in which kidney activity is impaired whether it be in the excretion of salt, water, or protein metabolites. As drugs are unfortunately of little help, treatment resolves itself into the maintenance of proper nutrition guarding against deficiencies in calories, protein, minerals, and vitamins. This is important because it has been shown that undernutrition increases the severity of the renal lesion.²⁰ Failure to maintain proper nutrition is a common error in the treatment of nephritis and this is most strikingly exemplified in the management of the protein intake. The presence of nephritis, hypertension, albuminuria or edema is commonly looked upon as an indication to withhold the much maligned meats and other protein foods. This régime is often followed by the development of lack of endurance, anemia, and other evidences of disturbed nutrition due to protein starvation. These symptoms are often looked upon as being due to the disease but they quickly clear upon the return to a normal well-balanced diet. The fact that there is certain minimal amount of protein necessary each day to prevent depletion of the body store of protein is completely lost sight of. It is usually considered that the minimum amount of protein on which a person can remain in nitrogen equilibrium is about 0.5 to 0.7 gm. per kilo,²¹ and no patient should be restricted below this figure except for a brief period. McCann and Keutmann²² gave patients with active hemorrhagic Bright's disease diets containing 75 to 200 gm. of protein a day without adverse effects. The important indications for restriction of protein are not albuminuria, high blood pressure, or edema, but definite evidence of difficulty in excreting protein metabolites, as shown by the elevation of the blood urea or nonprotein nitrogen and failure of the kidney to concentrate to at least 1020. When these criteria are lacking a normal protein intake should be allowed and when restriction is indicated it should not be below the minimal figure. The old idea that red meats were more harmful than white meats and that animal protein was more harmful than vegetable protein has been discarded; all proteins are the same to the kidney. When considerable albumin is lost in the urine each day and the plasma protein is lowered to below 4 per cent a protein intake of 150 to 200 gm. may be necessary. High protein diets are not permissi-

ble if there is inability to concentrate or an increase in the blood urea or nonprotein nitrogen is present. Hence it becomes evident that in some cases of Bright's disease a normal protein intake should be allowed; in others it should be restricted, and in still others it should be increased. In chronic nephritis without edema the normal daily intake of fluids must be increased because the kidneys can only eliminate solids in a very dilute solution. Hence, considerable water is needed to perform their work, and for similar reasons these patients should not be treated with hot packs as is commonly the case especially in uremia. Diuretics have no place in the treatment of nephritis, except when edema is present, and here the acid types of diuretics²³ are often efficacious, together with the limitation of the intake of salt and water. An effective method at times of initiating the excretion of urine in patients with anuria due to nephritis is the intravenous administration of a 20 to 30 per cent glucose solution. Patients with acute nephritis should be thoroughly investigated for foci of infection particularly in the tonsils. If these foci are found they should be eradicated but only after the acute process has subsided. In the treatment of the albuminurias incident to pregnancy and acute infections there is no justification for the restriction of the protein intake unless impaired renal function can be demonstrated. The convulsion and other nonuremic cerebral manifestations of glomerulonephritis and hypertension can best be treated by lumbar puncture to relieve the increased intracranial pressure and by depleting the cerebral edema with hypertonic solutions, particularly magnesium sulphate.²⁴

The treatment of patients with hypertension is often severe, harmful and to no point. Protein restriction is commonly prescribed without the slightest evidence of impaired kidney function. All that has been said here regarding the protein intake in nephritis applies to hypertension, and with greater emphasis because only a very small percentage of these individuals have more than a slight impairment of renal function. The mismanagement of the protein intake is no doubt due to the older views that nephritis was the cause of high blood pressure and that protein should be restricted in all forms of Bright's disease. Except for those few cases having impairment of kidney function, a protein intake of about 1 gm. per kilogram should be al-

Some Dangers of Socialized Medicine

A practical way to size up the value of socialized medicine is to look about us and see how it has worked elsewhere. Certain groups of doctors, we learn, now say that socialized medicine is coming anyway, so we might as well give up the fight against it. They argue that if all the doctors can be placed on a payroll at \$3,000 a year each, they will be better off, on the whole, than now. Like many other beautiful visions of a socialistic state, this one is very rosy, but will it bear the cold, hard light of fact? Is it possible that after the machinery is all set up the doctors may find themselves in the same situation where the school teachers are at present: their pay cut to the bone, till many are living in attic rooms, cooking their own meals, patching their clothes, accepting charitable gifts from the townspeople and with the pay checks anywhere from a few months to a year behind. City and state governments everywhere are virtually insolvent, and if this pitiful fate can happen to the teachers, what would prevent it from happening to the doctors? Who would or could guarantee that \$3,000 a year, or any other sum?

Would the defiling hand of politics, too, be kept off a system that would so clearly handle large sums of money and provide jobs for so many appointees? Many schemes of socialized medicine have sprung up around the country since the report of the Committee on the Costs of Medical Care turned the public thought in that direction. They often take the form of "health insurance" and have blossomed most prodigally in the golden State of California, a state that has been sorely afflicted by quacks of all kinds, medical and otherwise. Authorities on medical economics pointed out years ago that such schemes might easily degenerate into "rackets" and it now appears that that is exactly what has happened. Thousands of trusting Californians were wheedled into paying \$1 to \$5 a month to these medical and hospital organizations, only to find when the time came for medical and surgical aid that the concern had suspended business and the money was gone. Nineteen men

have been indicted by the grand jury of one county, but only three have been located. This is partly due to the fact that the action of the grand jury came nearly a year after the facts were known, indicating, it would seem, some sort of corrupt political influence. If the whole medical machinery of the country were in the hands of the bosses, what would the situation be?

Let us look next at Germany and its well-known *Krankenasse* or health-insurance system. We find an enlightening article about it in a western medical publication by a writer who seems to know what he is talking about. Like many other schemes, its purpose is splendid, but human nature enters in to take advantage of its defects. The law provides that a worker who is certified by a physician to be too ill to work is entitled to be laid off on half pay for as long as 26 weeks. So a man who is dissatisfied or tired of his work goes to his doctor and asks to be "written sick." If the doctor refuses, he changes doctors till he finds one willing to oblige. Doctor and patient lose the old-time personal touch. They are mere cogs in the machine. The ambitious young physician, burning to make great discoveries and work miracles of healing, finally becomes a mere automaton, writing orders and reports, orders and reports, day after day, week after week. The crowds of patients he has to see leave him exhausted, with no time or strength for reading, much less for original work. His salary, too, is pitifully small, because the funds are eaten up by the immense overhead. As many lay workers as physicians, it seems, are on the pay roll.

The patients, too, are victims of this attempt to create health by bureaucratic machinery. The physician has to see something like 50 patients in his two hours of office consultation in order to make a living wage. That figures out at about two minutes to each patient. We all know that the German doctor is faithful, earnest, efficient, and no doubt gives his best under these terribly adverse circumstances. The aim of the system, too, is of the highest character. But "the best laid plans of mice and men gang aft agley." With these

Eye Trouble and "Aye" Trouble

A defect of the eye has just been discovered by Professor Ames of the Department of Optics at Dartmouth which has no doubt existed for a long time without anyone knowing anything of it. The discovery explains a lot of things that folks have been wondering about. It seems that to the victim of this defect an object appears of one shape and size to one eye and another shape and size to the other. It is really quite common, the Professor assures us. In fact, something like one-third of all cases of eye trouble he has examined have it. If that is true, it must be that many have it who think their eyes are perfectly normal. Yet all the time they are seeing things one way with one eye and another way with the other. When they look with one eye an object seems enormous. When they look with the other, it seems like nothing at all.

We evidently have some victims of this malady at Washington, at Albany, and at various State capitals and in the City administrations. The Committee on the Cost of Medical Care were so badly afflicted that when they looked at the voter who has a pain now and then, he appeared as big as an elephant, but when

they turned the other eye on the doctor they just couldn't see him. Various cities and counties are erecting huge hospitals where every relative and friend of the politicians are to have free board and treatment, while the doctors are expected to give their services gratis. It is seeing big and seeing little again.

Professor Ames calls the disease "aniseikonia," from Greek words meaning "unlike images." It is said to cause nervousness and make the patient sick at the stomach. The one who has been the most patient in all this long discussion of the cost of medical care has been the doctor, and the habit of the authorities who see the voter big and the doctor little not only make him nervous and cause a feeling of nausea, but give him a severe pain in the neck region.

The politicians are proceeding at an alarming rate along the road that leads to the socialization of medicine, and it will not be long before measures looking in that direction will be coming before the State legislatures. Then the eye trouble will develop into "aye" trouble. Powerful forces will be behind these measures. All that the doctors will have to do to insure their success will be to do nothing. When the physician wakes up to find that he is only a hired man, sent here and there by some civilian official, it will be too late. The legislators, under the political whip, will vote "aye," and the mischief will be done.

Any other body of workers threatened by adverse legislation would deluge their Congressmen and State lawmakers with telegrams and letters until they turned the right eye on the matter and saw things in the proper proportion. It is time to take a lesson from the organized bodies of workers and war veterans, whose perfectly legitimate appeals to lawmaking bodies have such amazing success. One letter from a big campaign contributor, too, works wonders. A letter from a lawmaker's family doctor would carry enormous weight.

These eye troubles and "aye" troubles are bad, but they are curable, and it is high time for the profession to get busy on them.

Some Dangers of Socialized Medicine

A practical way to size up the value of socialized medicine is to look about us and see how it has worked elsewhere. Certain groups of doctors, we learn, now say that socialized medicine is coming anyway, so we might as well give up the fight against it. Let us look next at Germany and its well known *Krankenkasse* or health-insurance system. We find an enlightening article about it in a western medical publication by a writer who seems to know what he is talking about. Like many other schemes, its purpose is splendid, but human nature enters in to take advantage of its defects. The law provides that a worker who is certified by a physician to be too ill to work is entitled to be laid off on half pay for as long as 26 weeks. So a man who is dissatisfied or tired of his work goes to his doctor and asks to be "written sick." If the doctor refuses, he changes doctors till he finds one willing to oblige. Doctor and patient lose the old-time personal touch. They are mere cogs in the machine. The ambitious young physician, burning to make great discoveries and work miracles of healing, finally becomes a mere automaton, writing orders and reports, orders and reports, day after day, week after week. The crowds of patients he has to see leave him exhausted, with no time or strength for reading, much less for original work. His salary, too, is pitifully small, because the funds are eaten up by the immense overhead. As many lay workers as physicians, it seems, are on the payroll.

The patients, too, are victims of this attempt to create health by bureaucratic machinery. The physician has to see something like 50 patients in his two hours of office consultation in order to make a living wage. That figures out at about two minutes to each patient. We all know that the German doctor is faithful, earnest, efficient, and no doubt gives his best under these terribly adverse circumstances. The aim of the system, too, is of the highest character. But "the best laid plans of mice and men gang aft agley." With these

examples before our eyes, should we not go a bit slow before we give up the American system that is vanquishing one fell disease after another as the gods of Olympus vanquished the giants, and is prolonging the life of men on the earth like the discovery of some magic fountain of the Arabian Nights? Nations have been deceived before now by pictures of roseate schemes that only turned to the ashes of disappointment. In all our hasty national plans of change, let us not be led to plunge into some error that we can never retrieve.

A New Journal of Digestive Diseases

It seems surprising that up to this time there has not existed in this hemisphere a monthly publication devoted exclusively to problems of the digestive system and nutrition. Articles in this field have been scattered through dozens of more generalized publications so that anyone wishing information had to make a wide search for it. In this journal and that, of a special type, have appeared articles on the work of the experimenter, the internist, the parasitologist, the surgeon, the anatomist, the neuropsychiatrist, the physiologic chemist, the pharmacologist, and the dietician, but how many physicians have had ready access to all these periodicals? Very few.

Now we have an attempt to bring together in one publication the findings of all workers in this vital field. The new magazine is called *The American Journal of Digestive Diseases and Nutrition*. Its Editor-in-Chief is Dr. Frank Smithies, of Chicago, and its Supervising Editor is Dr. B. S. Carnell, of Fort Wayne, Ind. It is divided into ten sections: Clinical Medicine—Diseases of Digestion; Nutrition; Parasitology; Roentgenology; Therapeutics; Allergy; Esophagus; Experimental Physiology; Abdominal Surgery; and Surgery of the Lower Colon and Rectum. Over one hundred physicians throughout the country make up its Editorial Council. This state is represented by Drs. W. A. Bastedo, A. A. Berg, Harlow Brooks, B. B. Crohn, C. G. Heyd, J. M. Lynch, H. F. Shattuck, W. H. Stewart, and M. F. Vorhaus, of New York City,

and A. H. Aaron and A. A. Jones, of Buffalo.

The new publication makes a greater effort at good looks than most medical journals, even going to the extreme of leaving large areas of blank white paper that might carry something useful. Two facing pages, for example, have 20 square inches of print and 184 square inches of white space. Nine of the 90 pages are title pages of the departments, with about six or eight words surrounded by an expanse of blank paper. Here beauty and usefulness are at war with one another, and it will be interesting to see which will survive. A happy harmony might easily be achieved, preserving both.

However, so much of good is in the new sister publication, and so much more is in prospect, that criticism may well be subordinated to best wishes for a long, happy, and distinguished future.

Counter Attack Against Diphtheria in New York State

While the usual fighting force arrayed against diphtheria is always in operation, it is occasionally necessary that the reserves be called into action for a more powerful drive. When the enemy gains even a little, is the time to deliver a counter attack. Thus, and thus only, may front lines be pushed more deeply into hostile territory. As will be seen in the article by Commissioner Parran of the State Department of Health which appeared in the April 15th issue of the JOURNAL, such a moment recently arrived. A slight increase in incidence of diphtheria through the State, instead of the desired decrease, occurred in 1933. A number of small explosive local epidemics were also reported.

With highly commendable decisiveness Commissioner Parran called together the members of the Anti-Diphtheria Committee which conducted a remarkably successful campaign in the five years 1926 to 1931. That board of strategy accomplished reduction of morbidity from the disease from 116 cases per 100,000 of population in the entire state in 1925 to only 20 in 1933, of mortality from 8.6 per

100,000 in 1925 to 1.1 in 1933. Its weapon was immunization, its fighting man the family physician.

Even though the present situation indicates only a slight creeping gain by the enemy, the Commissioner has again mobilized, wisely, the entire army held in reserve. That army has experience and training in method; and it has gone to the attack without delay. The physicians are under direction of Dr. Farmer's State Society Committee on Public Health through the usual County Society channels; the Metropolitan Life Insurance Company is again working through its agents and nurses; the State Committee on Tuberculosis is again conducting a poster campaign of publicity; the State Department of Health is making a house-to-house canvass by its lay workers and nurses.

Nurses and Epidemics

Great epidemics in the past called for the help of hundreds of nurses who fought, often in vain, to stop the inexorable march of communicable disease. To-day nurses by the thousands go quietly about, from home to home, halting epidemics before they start. There is no beat of drum or fanfare of trumpets about it, but how infinitely more effective. In the old days the nurse was splendid at fanning the fevered brow, giving the drink of cold water, and gently closing the eyes of the dying. Now she discovers the case in its early stages, teaching the family how to care for the patient, calls in the doctor, isolates the sufferer for the good of himself and everybody else, and before the month is out the victim is able to sit up and take a little nourishment. No heroics, no medals, but the community may have been saved a string of funerals just the same.

A big part of modern nursing is to keep well folks well. The nurse has to be a teacher. She instructs an entire community in the art of taking care of itself. Like big children, they forget their lessons, an epidemic shows its head, and then she trains the mother to do what is best for her ill family. Mother's idea may be to give the baby something out of the big bottle of patent medicine she keeps on the shelf

for all ailments. Then the nurse must persuade her to call the doctor, and must become his assistant to see that his directions are carried out and to aid in prophylactic measures for others who have been exposed. She reports suspected neighborhood cases and in casual gossip discovers many that an investigating health officer would never find. If the situation looks bad, she lends a hand in campaigns for immunization against smallpox and diphtheria. She saves from illness and maybe death dozens or scores of people who will never appreciate it or thank her for it. She knows it, but it doesn't disturb her any. When her day is done, she changes to a very becoming frock and hat, powders her nose, and goes to the movies. Next morning she is hard at it again.

She cannot be everywhere at once. Some of the patients have no one to care for them, and she cannot stay, with an entire community on her heart and hands, so they must go to the hospital. Some one has figured out that contagious disease cases visited by the Henry Street Nursing Service in New York City cost \$7.13 per patient for the entire illness, while the expense per case at the Willard Parker Hospital ran to \$85 for measles, \$111 for diphtheria, \$194 for whooping cough, and \$234 for scarlet fever. The death rate, too, was lower in the contagious disease cases cared for by the visiting nurse service, although we must remember that it is often the more severe cases that go to the hospital.

It is disappointing, in view of all this fine record, to learn from the State Department of Health that there are sections where there are no public health nurses whatsoever, and many more sections where the nurses have such large territory that they can make practically no demonstrations of actual nursing in the home. Printed directions are not enough. Demonstrations are necessary. Two visits, or even one, may be sufficient, but they should be provided for every case of communicable disease in a community, no matter whether the patient be rich or poor. Every community should maintain this service in mere self-defense. As the State Department of Health well says: "If a nurse

saves the life of one child, the community will be richer by many times the salary of that nurse."

Twilight of the "Practical" Doctor in Germany

The uneducated "practical" doctor of Germany is to become educated, the "natural" medicine man is to have a scientific training, the rough and ready healer must learn a little more about the delicate and mysterious human organism he is treating. That is the decree of the new Nazi government, and the legislation to accomplish it is said to be now on its way through the mill.

Everyone knows that it has been legal in Germany for any person, educated or not, to practice the art of healing, on the idea that some are "natural-born" doctors, who understand by a sort of sixth sense how to diagnose and cure disease. These lay doctors are known as Heilpraktiker, and number only 4,280. They held their first congress last November.

Now they are to be regulated, like everything else in Germany. They must be German citizens of Aryan extraction, not married to non-Aryans, must belong to the League of Heilpraktiker, and be approved by the Minister of Health. They will not be permitted to enter the field of health insurance or public health work, or to treat venereal diseases, practice obstetrics and surgery, or give certain potent medicines.

The twilight of their day, however, seems to be indicated by regulations for their education, which reveal that the former uneducated healers are to have no place in the new Germany. If a "natural-born" healer is good, it will make him all the better if he knows a few facts about his patient's organism—that seems to be the simple logic behind the new law. Thus, as the legislation is outlined by the Berlin correspondent of the *Journal of the American Medical Association*, the applicant must have served one year as an attendant on the sick in an approved hospital. Then he must take a three-year course in a recognized medical school, pass an examination, and serve a year as a hospital intern. Even then he is only a Heilpraktiker. If a young

man who feels the urge to heal the sick must go through all this preparation to be a mere bush-leaguer, as it were, why not put a little more time and effort into it, and be a real doctor? That conclusion seems inevitable, and if the Heilpraktiker themselves do not see the handwriting on the wall, the plain trend of the legislation is toward later regulations that will do away with them entirely. A really practical doctor is an educated doctor. An uneducated "practical" doctor is impractical.

Freshets that Bring Disease

Physicians and health officers are warned to be on their guard at this season of the year against epidemic diseases that have their origin in polluted water supplies. The melting snows and abundant rains cause the tiny rills and rivulets that feed our reservoirs to swell into raging torrents. They burst their banks and spread over adjacent territory, picking up any contamination that may be lying about and bringing it on the run to the public water supply, where it may work mischief if not detected and guarded against.

If cases of typhoid fever, dysentery, and diarrheal troubles appear without any other apparent cause, the water supply may well fall under suspicion and warrant investigation. The water supply of dairy farms, too, is equally liable to contamination during the spring freshet season, and everyone who has to do with the people's health should keep that well in mind if an epidemic starts. It is, of course, gratifyingly true that the protection of public water supplies nowadays is far superior to what it was forty or fifty years ago. A germ that gets past the health officials has to step spry. But we all know that they do slip by sometimes.

The good old precaution of boiling the water then comes into vogue, or chemical treatment is resorted to. A bulletin of the Metropolitan Life Insurance Company reminds us that following the wholesale inoculation of the inhabitants of the flooded areas of the lower Mississippi Valley in 1927, the deaths from typhoid fever were less than one-third of the average for the

previous five years, despite the greater danger of infection.

What Noah drank after the Flood is well known to all biblical students, and no doubt many of the more convivial to-day would willingly avoid bacterial perils by giving up water entirely, and following Noah's lead. But our bacteriologists and health officials, at any rate, are giving them less and less excuse for it.

Cut-throat Medical Competition

One of the deplorable features of the depression has been the competition for contract medical work which has led in some parts of the country to underbidding, solicitation, and abuses of various kinds. It is true that we can hardly blame needy physicians for going to any legitimate lengths to support their families, but it is also true that competition of a cut-throat character injures the whole profession and must be halted if it is in the power of the state and county societies to stop it. It is not charged that all or even a large part of those in contract work are involved in this injurious underbidding, but it is evident on a moment's thought that the ethical may be ruined by the unethical; therefore it is a matter of everybody's concern, and we are told that nearly 48 per cent of all practicing physicians in the United States are engaged in some form of contract practice. Some are school physicians, some are medical examiners for insurance companies, some are in lodge or fraternal work, others are in compensation service, or look after the health of large groups of employees and their families.

The salaries or fees of doctors in these lines of service have suffered badly during the business slump, as has been natural and inevitable, but the reductions have been made worse, it appears, by underbidding and solicitation. It may be that there has been little or nothing of this sort going on in New York State, but it has been so flagrant in some other parts of the country as to call for severe disciplinary action. The situation in St. Louis is told in an article in *Medical Economics*, where the County Medical Society has created a Code and Contract Board to handle it.

The St. Louis Board has the power and the duty to investigate any and all written or implied contracts for medical service made by any member of the society. If these contracts are unethical, the member may be brought before the Censors Committee, and if convicted of unethical conduct, he may be suspended from membership. Conduct considered unethical includes direct or indirect solicitation of patients, underbidding, compensation inadequate to assure good medical service, prevention of free choice of physician, etc. The member is given a reasonable time to correct any objectionable practices.

The black list embraces not only erring physicians, but the institutions that employ them. The Code and Contract Board draws up a list of approved clubs, lodges, hospitals, clinics, and other institutions that use medical service under contract, and the approved list "shall receive the support and endorsement of the members of the society," according to the official resolution. Members who serve in institutions not on the approved list "shall not be in good standing if they continue their support." Another interesting provision is that "the Board shall adopt policies to insure remuneration for services rendered by the profession to institutions supported by public or private funds, taxes, endowments, etc." Gratuitous services to the indigent, of course, continue.

How far this evil has extended is unknown, but the depression has been so long and severe that it would not be surprising if doctors in many parts of the country had been driven to a kind of competition they would never seek in ordinary times. Once in this sort of thing, it is hard to get out. Business is now on the up-grade, and with the helping hand of their County Society behind them, working on the St. Louis plan, they may be able to rise to higher levels. As in another well-known case, the "Spirit of St. Louis" may take them to their goal.

A writer in *Hygeia* suggests that the apparent increase in cancer may be due to the fact that more cancer is recognized to-day than ever before.

The Recent "Floating Congress" of the Pan American Medical Association

Statements by Leading Physicians on Their Observations of This Trip

Dr. Chevalier Jackson, President of the Pan American Medical Association said: "The Pan American Medical Association has no political, religious, racial, or commercial aims. It is a purely scientific body of medical men. It is intended only as a means of discussion and of effort at solution of many problems of medical science. For example, some diseases like cancer must be studied in all countries, and comparisons made at international meetings of physicians. Other diseases may be prevalent in one country and not in another. For example, amebic dysentery is usually regarded as a disease of the tropics. It has invaded the United States; and we wish to learn all that our confreres in the tropics know about it. Other diseases call for international control. Before such control can be established, scientific research and discussion by physicians are necessary. These are only a few of the many phases of our work. Many social features were arranged by our hosts. The trip over the Andes by automobile on perfect concrete highways, as guests of the Government of Venezuela was a memorable one. This highway is a gigantic engineering feat that has rendered this magnificent mountain region of easy access. We were royally welcomed in all of the countries visited."

Dr. John O. McReynolds of Dallas, Texas, retiring President of the Pan American Medical Association said: "The Floating Congress of the Pan American Medical Association has marked a new epoch in the realm of international science and international goodwill. The universal sentiment of those in attendance is that a fresh stimulation has been given to medical progress under the most favorable conditions for personal contacts and cultural development. In all of the countries visited on this cruise, there has been a most cordial response on the part of the medical profession, the several Governments, and the general population of the different nations. The influence in the promotion of a better understanding and a closer international relationship will surely be definite and enduring."

Dr. William D. Haggard, Professor of Surgery, Vanderbilt University, Nashville, Tenn., and President of the American College of Surgeons, declared: "The Floating Congress was the largest medical gathering ever held before comprising two scientific weeks, totaling 175 papers with profuse moving picture illustrations of the newest and best in surgical art and superlative from a medical standpoint. The amortization of the medicine of all of the Americas was an

epoch in Pan-Americanism. A voyage of peace, carrying beneficence to millions, is the truest idealism and surpassed the Spanish Armada in its humanitarian endeavors. The Pan American Medical Congress embraces the outstanding surgeons in all the Latin Republics and amalgamates the science of the old and the new world in its far reaching crusade against disease."

Dr Lewellys F Barker, Johns Hopkins University, Baltimore, Md., stated "The Pan American Medical Association cruise has, in my opinion, been a great cruise, under the Presidency of Dr John O McReynolds of Dallas, Texas. It has not only brought many medical men of the United States together, but it has given them an opportunity of meeting in a scientific and social way a large number of the medical men of Mexico, Central America, and South America. The scientific papers read were of the highest order and the discussions illuminating. Every one on the trip seemed to feel sure that the Pan American Medical Association is performing a most useful function in cementing bonds of friendship among the medical scientists of the Western Hemisphere."

Dr Harlow Brooks, Professor of Medicine, Bellevue Medical College, New York, said "The most remarkable feature of the trip has been the cordiality with which we have been received at every port at which we have stopped. The second most striking feature of the cruise has been the excellence of the papers presented, especially on the boat, and the close attention to the professional phase of the work by all the sections. Also a very remarkable feature has been the exceedingly fine demonstrations and exhibitions presented by the physicians ashore. From my own part, I must particularly mention the exceedingly remarkable exhibitions given us in Puerto Rico. These are of inestimable value, especially

to those of us interested in tropical disease and tropical problems."

Dr Bernard Sachs, President of the New York Academy of Medicine New York said "This floating Congress has been an unqualified success, it enabled the members of the Pan American Medical Association to meet distinguished colleagues from Cuba Panama Colombia Venezuela, and Puerto Rico, with important men and women in all these countries the influence of the congress will be all to the good in strengthening the bonds of friendship between the people of this Western Hemisphere. Above and beyond this, this Congress has brought together men and women from all parts of the union in the various specialties, and has afforded numerous occasions for exchange of ideas between groups of medical and surgical specialists such as no other Congress has ever afforded. Personally I feel that the scientific sessions have been of a high order of excellence, and more stimulating than any congress I have ever attended. Add to this the unusual opportunity for a complete relaxation from the routine of duty, for stimulating companionship, and it is certain that the floating congress will become increasingly popular."

Dr Hugh H Young, Professor of Urology, Johns Hopkins University, stated "Others have spoken of the great success of this floating congress. The cruise not only removed North American medicos from the terrors of an awful winter, but it relieved the ennui of an ordinary cruise by scientific interest and instruction of great value. A most important innovation was to have the various specialists meet together in four groups. This was of value in that they learned of the great advances which have been made in other lines. Only good can come of medical and social intercourse with our Latin American colleagues."

THE YOUNGER HAVING A BETTER CHANCE TO GROW OLDER

The death rates for the several million policyholders of the Metropolitan Life Insurance Company in the United States and Canada show a decrease among children and young adults and an increase for middle life and old age. The company's *Bulletin* tells us that at ages 1 to 4 the death rate in 1933 among white children was less than one third of the 1911 rate, and among colored children, one fourth the earlier figure. The declines in later childhood and adolescence are only a little less than these. Continued improvement is also shown in the death rate of young adults. For the important working ages, up to 45, the 1933 rates for white persons were only one-half of those of 20 years ago, while the decline among young colored adults was one fifth to one third.

The death rates for middle life and old age tended to show increases in 1933 except among the white women. Although the rate for this

age group was lower than that for 1911, no improvement has been shown during the last 12 years, and at the older ages, particularly among men, the rate has actually increased.

Substantial mortality declines since 1911 were shown in tuberculosis, pneumonia, pregnancy and childbirth, diphtheria, measles, whooping cough, and typhoid fever. On the other hand, cancer, diabetes, and heart disease recorded higher mortality in the older age bracket than ever before.

The doctors in China are getting too rich, so a bill has been framed at Canton, and is considered certain to become law, limiting the doctor's fee to \$1.00 for the first consultation and 40 cents for every later one. The rule is to apply to both foreign and native physicians. Under this law the famous patient who said, "Well, doctor, here I am again!" would save only 60 cents.

Books

BOOKS RECEIVED

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

The Single Woman.—A Medical Study in Sex Education. By Robert Latou Dickinson and Lura Beam. Octavo of 469 pages. Baltimore, Williams & Wilkins Company, 1934. Cloth, \$5.00. (Medical Aspects of Human Fertility Series, issued by the National Committee on Maternal Health, Inc.)

The Foundations of Psychology.—By Jared S. Moore, Ph.D., and Herbert Gurnee. Second Edition, revised.

Octavo of 287 pages. Princeton, N. J., Princeton University Press, 1933. Cloth, \$3.00.

Das Wunder der Heilung durch Eigenes Blut.—By Dr. Ludwig Sternheim. Octavo of 64 pages. Bern, Switzerland, Hans Huber [c.1933]. Paper, Fr. 3.50.

La Lutte Internationale Contre le Cancer.—By Dr. Jacques Bandaline. Octavo of 947 pages, illustrated. Paris, Norbert Maloine, 1933. Paper Fr. 135.

BOOKS REVIEWED

Food, Nutrition and Health.—By E. V. McCollum, Ph.D. and J. E. Becker, M.A. Third Edition. 12 mo. of 146 pages. Baltimore, E. V. McCollum & J. E. Becker, East End Station [c. 1933.] Cloth, \$1.50.

According to the author, the aim of this popular book is to enable the reader "to detect the misinformation now being so widely disseminated by faddists."

The reader may be interested to learn how changes in climate or in geographical location govern differences in diets or influence the physical developments of various people. With such a panoramic study one wonders why we Americans who are constantly seeking perfection in diet have little to show for our intense efforts. The relation of diet to dental caries is convincingly discussed. This comprehensive book written in an abstract manner does not poison the layman's mind with meaningless diets and may well serve to supplement the physician's efforts in serving to inform the layman as to the meaning of food and nutrition.

EMANUEL KRIMSKY.

Infections of the Hand.—A Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand and Forearm. By Allen B. Kanavel, M.D. Sixth Edition. Octavo of 552 pages, illustrated. Philadelphia, Lea & Febiger, 1933. Cloth, \$6.

The sixth edition of "Infections of the Hand" is with us. It has become medical tradition to associate with certain things the name of the master. Circulation immediately recalls William Harvey, ligatures, Ambrose Paré, and infections of the hand, Allen B. Kanavel.

The book is more profusely illustrated than ever before. The systematic arrangement is the best possible. What more need be said? This book is the vade mecum of the surgeon and general practitioner.

ROBERT F. BARBER.

Manual of Urology.—By R. M. LeComte, M.D. 12mo. of 317 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$4.00.

This little book is exactly what it purports to be and no more. It is a manual designed for students and should be of value to any student reviewing the subject and preparing for an examination. We do not think it would be of any interest or value to the practitioner.

N. P. RATHRUM.

A Text-Book of Medicine.—Edited by Russell L. Cecil, M.D. Third Edition. Octavo of 1664 pages. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$9.00.

The third edition of this standard text on medicine was made necessary because of rapid advances in internal medicine since the publi-

cation of the second edition, only three years ago. Many of the older chapters have been revised and rewritten by the authors. New articles have been added on subjects more recently discussed, especially upon the ductless gland system.

As a textbook and reference work, this volume is preëminently one of the most valuable and is recognized as such. It contains a seemingly endless store of necessary, accurate information, well written and well presented. From a typographical point of view the volume is excellent, good paper, clear printing and easy to read. For one to keep in touch with the present knowledge of medicine, this volume is indispensable.

HENRY M. MOSES.

Blood Pictures.—An Introduction to Clinical Hematology. By Cecil Price-Jones. Third Edition. Octavo of 72 pages illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$2.40.

The third edition of Price-Jones' book includes some of the more recent advances in hematology. It presents, in concise form, for the general practitioner, the methods of blood examinations and the description of the normal pictures. The colored plates are exceptionally well done. Although the English terminology is adhered to, only slight confusion is entailed. Perhaps the greatest deterrent to its wide acceptance is the price, which seems to be rather high for so small a volume.

MAX LEDERER.

Mayou's Diseases of the Eye.—Fourth Edition revised and largely rewritten by Frederick Ridley, B.Sc., and Arnold Sorsby, M.D. 12mo. of 249 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$2.25.

This pocket-sized volume indicates from its mere dimensions that one must not really expect an elaborate discourse on "Diseases of the Eye." Such a work might serve as a guide to introduce a student to a more elaborate book, but unfortunately certain peculiar classifications as set down by the authors make it impossible to coordinate their teachings with those met with in more extensive works. Thus phlyctenular ulcers are classed as suppurative inflammations of the cornea as is also keratomalacia. Chronic glaucoma is said to be found but rarely under fifty years of age.

The illustrations do not lead to elaboration of the statements set down in the text.

The reviewer cannot endorse a work the object of which is obscure. The preface does not state the purpose for which the book was written.

JOHN N. EVANS.

THE PRESIDENTIAL ADDRESS**FREDERICK H. FLAHERTY, M.D., SYRACUSE, N. Y.**

Members of the Medical Society of the State of New York, Invited Guests:

Since you have honored me with the office of President, I have studied with increasing interest the origin, history and purposes of this Society. It is with considerable pleasure that I have reviewed its early transactions and history. One cannot help being impressed by the high ideals, lofty principles, and broad vision of the leading men who were the pioneers in the organization of the Medical Society of the State of New York.

In the early days of the 19th century medical practice was chaotic. There were no particular regulations. Quacks, pretenders, and all sorts of men attempted to practice medicine. It is true, colleges were established in Philadelphia, New York, Boston, and other centers which developed a few high-grade physicians, but there was no organization to control or educate the man who desired to care for the sick. The main thought of this Society, therefore, was the betterment of medical education and the regulation of the practice of medicine.

These early members were not only educated in medicine but showed considerable knowledge in all the sciences. They realized that regulation of the practice of medicine could only be obtained by the authority of the State and so applied to the State Legislature. The authority was granted and the Medical Society of the State of New York was created.

In reviewing the transactions of this Society from the first meeting in 1807, one is impressed by the fact that organization and the better training of the physician

were their main objectives. The transactions abound with efforts to strengthen and fortify these principles. They early established the policy of prize essays in order to stimulate study, research, and observations of important cases. In the transactions many creditable essays and observations are recorded which show not only clear reasoning but excellent judgment.

Dr. Thomas Spencer of Madison County, President of this Society, presided at the 28th Annual Meeting in February 1834. The Medical Society at that time consisted of one delegate from each of the fifty-four counties, one delegate from the College of Physicians and Surgeons in New York City, twenty-six honorary members, and thirty-one permanent members. The honorary members represented outstanding men of the country, of which the Society elected two each year. The permanent membership consisted of men who had served as officers or delegates of the State Society, and two such members were elected each year.

The charter designated the first Tuesday in February as the date for the Annual Meeting and that it should be held in Albany during the session of the Legislature. The meeting was held at the Capitol. The annual address was given in the Assembly Room by permission of the Legislature. Six seats were reserved for members of the Legislature indicating that our early members were good strategists as well as delegates. Thirty-one delegates were present.

I can visualize these delegates, three or more days previous to the meeting, arranging to start by coach or on horseback over

rough country roads, some covered with snow, coming from the various counties to Albany. The only railroad at that time was the one from New York to Albany with the extension to Schenectady. Transportation was primitive, the locomotives burning wood. The trip from Ontario, Jefferson and other remote counties required considerable fortitude. How many of our delegates to-day would make such a trip on horseback or by coach? Yet, these pioneers did attend in goodly numbers.

Arriving in Albany they gathered at the tavern. The accommodations were crude in midwinter—fireplace in the main lounging room, iron wood-burning stoves to heat the room, lighted by candles and no bathroom facilities within the tavern. On awakening in the morning the washbasin frozen with a thin layer of ice. After breakfasting, wearing their high leather boots, they trudged up the hill at Albany to the legislative hall. The legislative hall was heated with the same type of wood-burning stoves. Their proceedings record that they conducted their meetings in strict parliamentary order and with much dignity. Two former members from Cayuga County and the President of the Albany County Society were seated as honorary members.

The session lasted three days. Besides the routine business, much important business was discussed. A communication was received from Dr. Joshua Lee, a member of the Legislature and Chairman of the Committee on Medical Societies and Colleges, covering two petitions to the Legislature—one from the Medical Society of the County of New York regarding an alteration on the mode of admission into said Society so that every applicant might be examined by them, and the other from the Medical Society of the County of Genesee praying for a law to prevent the spread of smallpox in the state.

It was resolved that a committee of three be appointed to report upon the propriety and importance of changing the time of the convention of the State Medical Society to the second Tuesday in January instead of the first Tuesday in February. This was done to enable them to get their legis-

lative bills in at the earlier meeting of the Legislature.

Mr. Green C. Bronson, Attorney-General of New York State, gave an opinion on the powers of the County Society relative to admission and expulsion of its members.

In the homespun piece of fabric, from which the pattern of this Society was cut, one can detect running through the great mass of material one golden strand which was ever present. The principal thought of the founders of this Society was betterment in medical education with regulation of medical practice so that humanity could be protected.

The development of bacteriology, the principle of asepsis, the scientific study of drugs, the numerous valuable principles produced by the physicist in the scientific laboratory have all been taken up by our profession and utilized for the benefit of mankind. Their great value is recognized by all. The wonder is how the physician ever got along without them.

In spite of the many improvements in our method of diagnosis—such as x-ray, electrocardiogram, cystoscope, dye test, chemical examination of various secretions, bacterial test of the blood and other secretions, etc., which were entirely unknown in those early days—these pioneers did make some very clever diagnoses, did save many lives and were well aware that 85 per cent of the ordinary ills were recovered from rest, diet, and good nursing. These men were of great value to their patients. If one will take the pains to review some of these cases recorded in the early transactions of the Medical Society of the State of New York, one will be delighted and greatly interested in the observations and deductions of some of those early members of our Society one hundred years ago.

At present we are facing many important problems, the solution of which will demand study, careful planning and much hard work. The medical colleges are turning out more physicians than can be used in the present state of society. The incomes of the masses have been lowered to such a level that the average physician in actual practice is not receiving more than half the income received in 1929. Lay-

men, social workers, health workers, politicians, department store owners, would-be reformers, economists, socialists, antivivisectionists, and even Herr Hitler in Germany are all trying to change the present method of medical care so that it will concur with their ideas.

I believe it is quite clear that we are opposed to so-called socialized medicine. It is quite evident that the term "socialized medicine" is a red flag to many physicians. It is quite true that we have state medicine in many forms which are accepted as a matter of course and no one seems to get excited about it. The care of the insane by the State, which we have had for the last hundred years, is a definite form of state medicine. The State Laboratory for the diagnosis and treatment of malignant diseases is truly state medicine. The manufacture and distribution of various vaccines, toxoids, and many other biological preparations, are state medicine. The hospitalizing of the indigent patient, paid for by the city, county or state, is state medicine. The building of county and state hospitals for the care of tuberculosis is state medicine. The hospitalizing and treating of our veterans in government hospitals is state medicine. To what form of state medicine is it that the practicing physician or doctor objects?

The family physician should be protected in all such endeavors that his training and education have prepared him for in the diagnosis and care of the sick and injured. He should be permitted to be in charge of and supervise all health examinations not only of school children but of adults, the administering of vaccine, toxoids, and other biological remedies. If we are going to continue the practice of medicine as now constituted—and by this I mean that the family physician will be retained as such to administer to the sick and injured, that he will be able to retain his patients as individuals—the formation of groups, either by lodges, insurance companies, or other forms of group practice, should be discouraged.

The depression has had one beneficial reaction on the practice of medicine. It has called the attention of the authorities to the fact that the sick individual, who

is indigent or near indigent, is entitled to proper medical care as other necessities such as food, clothing, and shelter and that they are obligated to pay for the medical care of the indigent as well as for their food, clothing, and shelter. It is very apparent, as written in the present Welfare Law and its auxiliary, the TERA, that for home relief the physician must be paid. This can be done by one of two methods: The Welfare Officer can authorize the family physician to care for, to operate upon, and to deliver pregnant mothers at their homes and at times in the hospital for a reasonable modified fee. This is very important. They cannot and will not pay unreasonable fees. If any individual physician in the welfare district attempts to graft, pad his bill, or charge unreasonable fees, the Welfare Commission has the authority to appoint a physician or physicians to do all the welfare work in the district. It, therefore, behooves every County Society in the State to have their Public Relations Committee contact the Welfare Officer and endeavor to keep their welfare work on a fee basis for those physicians in the County who wish to render the service on a reduced fee basis thereby retaining their patients who, in better times, will return to them and again become pay patients. The so-called Vaughn Plan, in which many activities such as vaccination, administering toxoids, pre-school examinations, etc., are planned, is not only economical but efficient.

We stand for the preservation of the family physician. We believe the Public Welfare Law, as it is now being administered in some of our Counties in the State, will greatly correct many of the abuses.

The research of the medical investigator has produced a system of health service which has changed our civilization, increased the average length of life at least forty years, thus rendering possible many of the great developments in industrial and commercial life. It cannot be denied that, if it were not for the investigations and research work of the medical men resulting in the control and, in some instances, the obliteration of disease which formerly decimated the human race, our civilization could not have developed to its present

state. The higher demands on medical education have stimulated medical research. It has developed men of a higher type in the profession. This in turn has placed the physician on a higher plane in society. Our organization has always stood for better education of the physician and the highest type of ethics. Over one hundred years ago our Society formulated a standard of ethics which has survived with the Society and which has been copied by many state and national associations.

Our country has changed in the past thirty years from a rural farming state, in which the farmer was comfortably taken care of, to a highly organized industrial empire. Transportation has made radical changes in our economic condition. Education has likewise been an important factor. Enormous moneys have been poured into schools and colleges so that a greater mass of young men and women go through high school and college. This has increased the number of young men for the professions.

In this State, as well as in the nation, there has been an enormous increase in hospitals—government, state, and municipal. This has added a large factor to the change in methods of practice of our profession. Our State has developed a health service which has brought the average mortality rate down to the lowest in the history. The depression of the past four years has brought about a service for the unemployed which had never been dreamed of in the history of our country. The change of the word pauper to welfare has rightly taken away the stigma of aid. The rapid changes of method of our government in eliminating welfare and terming it CWA gave the unemployed the feeling he was working for the government which is true.

All of this is being accomplished by use of public funds. There is only one method for raising public funds. Public funds come from taxes either directly or indirectly. In April, 1933 there were 396,884 families on relief rolls. This is 15 per cent of the population of our State. This group of individuals must be rendered medical care when sick. Under the TERA state medical care, food, clothing, and

shelter are listed as necessities of life. Under the terms of the law the State establishes relief standards and reimburses the local welfare district for approved expenditures on account of unemployment relief including medical relief. A large number of our profession are asking and demanding that the physician be paid for all services rendered to that portion of the public—indigent, near indigent, dispensary patients, and hospital patients commonly known as ward patients—who cannot pay. There is justice in this demand. The physician should have the same consideration as do other citizens who are paid for services rendered or for goods sold.

Our Public Relations Committee has aptly expressed it: "Compensation to protect physicians against economic loss is rightfully expected and should be provided from public funds." The Welfare Departments in all the larger cities are paying the physician or physicians a salary for the care of the indigent. The purpose of this arrangement, I assume, is to better budget their funds. It has many objections. First, a practicing physician, who has a salaried job, usually takes care of his private work at the expense of his salaried work. This is only human. Secondly, it often occurs, if an indigent person is very ill or demands too much attention, that the case is sent to the charity wards of the hospital causing the city to pay for double service. Thirdly, too often the city physician is a political appointment, is not appointed for his ability but for his political influence and, as a result, gives inferior service. Fourth, a physician on a fee basis will always respond more promptly than one on a salary.

It cost the forty-one cities in the State of New York, which employed salaried physicians, \$103,667.56, according to the Mayors' conference on October 31, 1933. This is approximately \$1,000 per man for the year.

Our Society should go on record taking such action, as may be necessary, to correct this system. Each reputable physician in his community is not only entitled to his share of such work but, as a citizen and taxpayer, should receive it.

Great changes are rapidly taking place in the daily life of each citizen of the country. We have been going through a social revolution during the past several years. The status of the producer has already been changed. The manufacturer no longer dictates his former policies. Banking has been modified and greatly restricted. All business is now being regulated as never before in history. Forces are at work which will change the relationship of the physician to the public. The whole status of the physician will be altered. There may be restrictions placed upon us that may not be to our liking. My attention has already been called to the fact that the policy of the government in paying for the indigent and those who are near indigent may easily be developed into the panel system such as exists in England and other European countries.

There are many honest substantial citizens who are feeling the burden of illness such as never before has been experienced. The echoes of the report of high cost of medical care are still ringing in our ears. Are we going to stand still and let others make rules which will govern us and our professional work? Every State Society

in the United States is working on these same problems. The American Medical Association has its committees at work. Our State Society is doing its part. It is incumbent upon each and every County Society to do its part if we are going to survive.

Fred Betts, columnist of the *Syracuse Herald* on April 14, 1934 commenting on an address by Dr I S Falk, research associate of the Milbank Foundation, says "Well, after the Federal Government nationalizes the power industry, thus relieving Senators and Assemblymen of the necessity of writing letters to utility officials, probably it will be medical rates that will come under the Albany legislative hammer. Indeed, the day does not seem very far off when any patient who objects to a physician's fee for treatment of snuffles, parrot fever or summer ailments will have a right to appeal to the Public Service Commission. How it will work out we do not pretend to know but, whatever happens, if present trends continue it seems likely that there will be a sufficient number of melancholia cases to keep the physicians going."

MEDICAL STUDY TRIP TO HUNGARY

At the invitation of the Hungarian Medical Postgraduate Committee of Budapest, Professor Emil de Grosz, President, and of the Association Budapest Town of Medicinal Springs," Archduke Dr Joseph Francis, President, a medical study trip to Hungary is being organized. The plans provide for a fortnight visit to Hungary during which there will be postgraduate lectures and demonstrations in English at the principal University clinics and at the municipal thermal baths and springs. Reduced railroad fares and hotel rates are granted by the Hungarian Govern-

ment. The party will sail from New York on August 18, 1934, visiting Munich and Oberammergau en route. The return trip may be made, optionally, via Berlin, Paris, or Italy, arriving back in New York on September 30.

American physicians of good standing are invited to join. The American Committee of the study trip consists of Harlow Brooks, M.D., Chairman, Charles G Kerley, M.D., Jerome M. Lynch, M.D., Wendell C Phillips, M.D., and Erwin Torok, M.D. Richard Kovacs, M.D., 1100 Park Ave., New York, is Secretary.

A huge institution for medical study and treatment is projected by the Soviet government, according to an announcement made in New York by Prof Nicholas J Krasnogorsky, Director of the Institute of Experimental Medicine in Leningrad, and one of the world's leading child specialists. It is to cost 120,000,000 roubles and plans are now being completed in New

York drafted according to American hospital practice. Twelve large buildings are contemplated, with 8,500 rooms for laboratories, wards, clinics, shops, etc., and with a staff of 3,500 scientists. The institution will be located in Leningrad, and is to be completed in two and one half years. It was first proposed, says Dr Krasnogorsky, by Maxine Gorley.

PSYCHOANALYSIS IN PSYCHIATRIC PRACTICE

BERNARD GLUECK, M.D.

New York, N. Y.

It is impossible in the space allotted to do adequate justice to any single one of the many features of psychoanalytic psychology, and what I am endeavoring to do here is to present the barest sort of bird's-eye view of the matter for a general orientation.

More than three decades have elapsed since Freud began publishing his findings. From the very first, his contributions challenged the traditional ways of evaluating the causes of man's failure to adjust himself to the requirements of life. These traditional ways laid considerable stress upon constitutional equipment, toxic, traumatic, and other noxious external agents which were considered adequate to account completely for pathological theory. The contributions of psychoanalytic psychology are compelling a radically different orientation to the problem of human maladjustment. The implications of this new orientation for the questions of etiology, pathology, therapeutics, and preventive medicine are very far-reaching and are exercising an increasingly important influence also upon somatic pathology and treatment. This new orientation has to do primarily with the changed conceptions concerning the nature of man, which the discoveries of psychoanalytic psychology made possible. I shall, therefore, present a brief outline of these conceptions. For purposes of clarity, I shall avoid as much as possible technical terminology and shall follow the hint of the late William James, namely, speak of the various aspects of the personality as of so many different selves.

There is, first of all, the conscious, the socially oriented and visible self, the self which is in constant contact with the realities of the external world—it is the self of brain and brawn, of education and experience, the initiator and executor of conscious motives, and the spearhead of man's impacts with the world about him. It is obvious that whatever other forces there may be that enter into the determination of attitude and conduct must function through this conscious self, since it alone

has direct access to man's equipment for dealing with the requirements of life. In the final analysis it is the strength or weakness of this conscious self which decides the issues of adaptation. In psychoanalytic terminology we speak of this "self" as the "ego." Now, it does not require any profound psychological insight to appreciate that this "self" of which we are speaking is not co-equal with the "somatic or physical self," the disorders of which constitute the chief domain of medicine and surgery.

We are able to obtain a glimpse of what the moving forces of human attitude and conduct are that lie outside of this conscious self, when we observe what happens in the case of the insane patient. Here the conscious self or the "ego" abandons control and submits to forces which were hitherto unsuspected by ordinary observation. The delusions and misinterpretations of the insane, the bizarre distortions of reality, and the symbolic actions speak a language which is unfamiliar to us from observation of the ego of the average normal individual.

This brings us to a consideration of the next "self" which enters into the structure of the human personality, the "instinctual self." This self, the expression of which in pure form in adult life is only visible in the dream and in certain pathological states, particularly in mental disease, has to be subjected in the course of individual development to a complicated and difficult process of taming, transformation, and socialization before it can be utilized in the service of the adaptive requirements of man. It is the self that is identical with the psychoanalytic concept of the "id," a hypothetical reservoir of primitive, egocentric, and unadjusted strivings that reflect man's kinship to the lower forms of life. The conscious "self" is the product of rearing, education, and culture; it reflects the impress upon the asocial, amoral, and unadjusted infant of his social environment; it is the evidence of the moulding influence which the social milieu exercises

upon the developing individual. Now the central objective of this environmental influence is the weaning of the developing individual from the lures and attractions of the egocentric, selfish, and asocial aspects of his instinctual self, with the view of adjusting it to the requirements of life in association with others. We might state parenthetically that the major concern of psychoanalytic theory and practice is with the developmental vicissitudes and destiny of the instinctual life. For many years after psychoanalysis came into being the sources of the conflicts at the basis of human maladjustment were considered to be covered by the antagonism between the conscious and the instinctual selves.

So-called normal conduct would then reflect the achievement of a workable and satisfactory adjustment between the two sets of claims for the control of the personality which the individual is obliged to pay heed to. These two sets of claims are antagonistic from their very inception, they are those of instinct or nature on the one hand, and those of nurture and culture on the other hand. Well-adjusted or normal conduct is possible only when the conflicts or antagonisms between these two sets of claims are reduced to a minimum. Excessive domination by either set of these claims is bound to cause maladjustment. We shall see later on how the particular form of maladjustment is conditioned by the specific and individual vicissitudes of this interplay of internal forces. But we have to consider a third self, which enters into the composition of the personality, the "super-self." The recognition and acceptance of this aspect of the personality, the "super-ego" in psychoanalytic terminology, was made necessary in connection with the increasing experience with psychoanalysis as an instrument of research and therapy.

It is conceived of as a part of the conscious self which becomes differentiated in the very earliest stages of individual development, and is then introjected and internalized, continuing to develop as the subjective and unconscious aspect of what we know consciously as conscience. It becomes the internal regulator and monitor of conduct, or rather of the ego's management of the life of instinct. An impulse to cruelty, for instance, which, if permitted free range, would lead the conscious self to the commission of a cruel act, is obliged, as are all other instinctual drives, to subject

itself to the scrutiny of this "super-ego" function, and its destiny is determined by the relation of the "super-ego" to the "ego," and naturally also by the quality of both of these aspects of the personality. Naturally this simple statement of the situation does not attempt to do adequate justice to the complexities of the structure and organization of the human personality. But it is, nevertheless, true that normal as well as abnormal states of the personality can best be understood from a study of the interplay of the subjective forces which we have for clarity's sake spoken of as "selves" in the foregoing description. It will become obvious as we proceed that this conception of man does not involve a neglect or negation of all those other factors which have in the past constituted pathological theory. It merely focusses attention to certain inevitable and universal sources of maladjustment which lie in the necessity of adjusting primitive biological tendencies to the requirements of social life.

We have already indicated that normality so-called, is after all a relative and not an absolute concept and reflects the achievement of a satisfactory and workable compromise between the contending forces for the control of the personality and conduct. It is entirely in accord with actual clinical experience to see in the various forms of personality maladjustment from the mildest to the most severe, different degrees of deviation from the state of affairs mentioned in the foregoing. The pathological deviation may be the result either of special qualities in the various selves which we have outlined before, or in the relationship between these selves. Thus, to begin with, individuals undoubtedly differ in the original strength, intensity, and plasticity of their instinctual heritage; they certainly differ in the character of the super-ego which experience has shaped for them, and it is well known that they also differ in the strength and quality of the conscious self or ego. Individual experience certainly is bound to affect the interrelationships between these various aspects of the personality.

Thus when we speak of the so-called transference neuroses, that is, the various forms of hysteria and the compulsion and obsessional neuroses, we speak of individuals who suffer because of an unmanageable intrapsychic conflict and in whom the symptoms reflect an effort at a symbolic

or substitutive gratification of instinctual drives which are tabooed and prohibited by the super-ego, or a defense against them.

The conscious or socially oriented self has not undergone any appreciable weakening or disintegration, but it is inhibited and interfered with to a greater or less degree because of its subjugation to a too severe inhibitory influence from the super-ego. The conscious self still possesses insight into the fact that something is wrong, it is capable of a considerable degree of autocriticism and consciously, at any rate, desires and seeks relief from its difficulties. But it is incapable of dealing adequately with the intrapsychic conflict. Its integrity is threatened "because for the maintenance of this integrity it needs, on the one hand, secure possession of certain sexual impulses, or their derivatives, and on the other hand, a secure relation to external reality" (Jones). There are significant differences in etiology between the hysterias and compulsion neuroses which need not concern us at this moment. But it is true of all forms of psychoneurosis that in a general way the claims of instinct or nature have experienced an unnecessarily excessive denial and restriction in response to excessive taboos imposed upon the individual by that side of his nature which reflects the claims of culture and nurture. The difficulties of the psychoneurotic are not due to frictions with the environment as such, but to an intrapsychic conflict. Insofar as the claims of society or culture constitute an element of this conflict, they have become internalized and to all intents and purposes part of the nature of the individual, and they have acquired a degree of significance and power equal to the significance and power of instinct itself.

The next large category of personality maladjustment embraces the various forms of psychosis or mental disease. Here the situation might be said to be quite the reverse of what happens in the psychoneuroses, without invalidating the conception that basically the same forces are at work as in the psychoneuroses. But here the claims of instinct assume ascendancy and are given free rein. Through the abandonment of the sense of reality and of autocriticism the claims of culture are increasingly ignored; psychotic thinking and behavior reflect a regression of libido

to the earliest narcissistic phases, the individual becoming indifferent to the claims of reality. The difficulty here is obviously primarily with the ego, and it opens the way for a helpful definition of the relation of psychoanalytic doctrine to the problem of organic or toxic etiology when we observe that the same state of affairs exists whether the damage to the ego is due to organic or toxic agents or to psychological developmental vicissitudes. In the case of the psychotic, the conflict is between the ego and reality.

There is still another fairly well differentiated category of personality maladjustment which has received very illuminating consideration psychoanalytically, the so-called "neurotic character." In this category belong the various forms of psychopathy, certain types of criminalism, and addiction. Before entering upon a discussion of the psychoanalytic conception of the "neurotic character," it might not be out of place to refer briefly to one important difference between physically and psychically conditioned disorders. Now, in connection with physical illness, the physician would be very much surprised if he were to encounter in his patients a resistance to getting well, say nothing of a wish to be ill. And yet this is a regular experience in dealing with psychologically conditioned difficulties or disorders.

The wish to be ill is a basic characteristic of psychically conditioned disorders, whether these be of a mainly psychological or mainly somatic nature. The isolated symptom, as well as the more extensively organized symptom complex, reflect the compromise struck between an egodystonic, forbidden, and untolerated instinctual drive and the opposition of the ego. This ego-opposition to the direct and unmodified expression of the unacceptable instinctual drive relents in the course of time and in connection with the necessity of doing something about the distress and anxiety produced by the conflict which initiates the necessity for symptom formation. As a consequence to the ego's yielding to an otherwise unmanageable situation the symptom or illness as a compromise formation is accepted and in time defended and protected by the ego. As long as the underlying conflict remains unresolved, the wish to be ill, to retain the compromises achieved by the illness, remains an indispensable characteristic of every psycholog-

ically motivated symptom or illness. This is what has been termed the epinosic or secondary gain of illness. Now a paradoxical situation emerges which must appear as a curious phenomenon, indeed, to those who see in pathological conditions the mere invasion of the organism by noxious agents, of which the individual naturally would wish to rid himself and whose cooperation with the physician's efforts in this direction should, of course, be taken for granted. The paradox disappears once we truly understand the difference in the etiological categories between a psychologically and a physically conditioned illness. In the latter case we are correct in speaking of causes, in the former it is more correct to speak of motives for the illness. In a psychically conditioned illness, there is an anterior participation on the part of the patient in the creation of the illness. The neurotic symptom is the best that the patient can do in his effort to deal with a distressing subjective maladjustment, but obviously it does not solve the underlying problem. Indeed, when one observes the painful anxiety, the crippling inhibitions, and defeats of the compulsion neurotic, coupled with an unrelenting and obstinate persistence in hanging on to these symptoms, one wonders what possible advantage there could be in this substitute for a preëxisting difficulty. But apparently the terror and panic which the threat of an emergence of an unconscious sadistic impulse induces render the acceptance of the painful and crippling system of defensive reactions of the compulsion neurotic desirable.

Moreover, the neurotic symptom as a compromise outlet for a forbidden instinctual drive must of necessity contain both the substitutive and roundabout gratification of the impulse and the punishment for its indulgence. The pain and suffering which accompany the neurosis are indispensable conditions for its utility in dealing with the conflict. Herein, the neurotic manner of dealing with forbidden instinctual or Id tendencies differs from sublimation as a way of dealing with similar tendencies. Sublimations are likewise substitutive gratifications of Id tendencies, but these tendencies, when expressed by way of sublimations, have undergone a sufficient degree of desexualization, their indulgence is no longer in conflict with su-

per-ego injunctions, and thus they escape their punitive impositions.

To sum up, a psychologically conditioned illness constitutes the compromise struck between the conflicting tendencies of Id and ego; or putting it in different terms, between the claims of instinct and those of culture. It is a compromise which the ego accepts only after great initial resistance. But once accepted, it is defended and protected by the ego, which is willing to endure the pain of the illness along with the substitutive instinctual gratification which it makes possible. The wish to be ill becomes indispensable under these circumstances as well as the resistance to cure which we encounter in these cases.

Now there seem to be some individuals in whom this initial ego resistance to the emergence in action of forbidden Id tendencies does not take place. The ego from the very beginning permits itself to be permeated and characterized by these tendencies, sometimes in a more or less modified state, at other times as direct instinctual expression. Obviously it is here a question of a serious miscarriage in super-ego formation in connection with an inadequate dealing with the Oedipus situation. This is what constitutes the neurotic character, those troublesome, inefficient and frequently dangerous individuals who constitute the greatest challenge to psychoanalytic therapy and here and there its greatest therapeutic triumph.

The simplest way of indicating the difference between neurosis and "neurotic character" is to say that the latter constitutes an asymptomatic neurosis when contrasted with a specific neurosis of the conventional type. Or one might say that the neurotic character's total life performance constitutes the symptom of his neurosis. The individual traits of character are so many attenuated, microscopic symptoms of the sort that we are familiar with in the conventional clinical types of neurosis. While the psychoneurotic mainly "suffers out," subjectively, so to speak, his symptoms, the neurotic character lives them out in his daily behavior. It is obvious that this distinction is a relative one only since there are certain vicissitudes of a subjective as well as an objective nature which are common to both. But in the main the neurotic character reflects the pathology of his nature in everything he does, whereas the psychoneurotic is able to

a greater or lesser extent to mobilize his illness in time and space relationships. Part of the ego of the psychoneurotic is able, so to speak, to stand aside and view objectively the illness. This determines the differences between the two conditions as regards insight and attitude toward treatment. As regards the latter aspect of the situation it is well known that a neurotic character trait has to be metamorphosed into a symptom before it can be successfully subjected to psychoanalytic cure. The neurotic character, because of the permeation of the ego with Id tendencies and its tolerance of them, readily rationalizes such personal or environmental critique as he may be confronted with and never really possesses true insight. Ordinarily he comes for treatment only through external compulsion.

A number of classifications have been proposed for the differentiation of the neurotic character. The best, to my mind, is still the more general, namely, that neurotic characters might be divided into two types, the impulsive and the reactive. The former characterizes those individuals in whom primitive, instinctual or Id impulses are permitted a good deal of direct outlet with little or no modification. They include aggressive, antisocial, and criminal reactions as well as unrestrained appetitive indulgences such as alcoholism and drug addiction and overt homosexual practices of a polymorphous nature, including heterosexual as well as homosexual compliances in the service of a more general ego gratification (bisexual prostitution). The second group is a reactive group in which the character traits and indeed the total make-up of the individual constitute a system of defense against primitive impulse without specific symptom formation. The picture is that of a profoundly inhibited and socially shy and inadequate individual who in response to strong masochistic urges lives a life of continuous maladjustment, more as a nuisance than an active disturber of the social environment. While unconscious guilt and need for suffering is a marked characteristic of the latter type, the former does not entirely escape a similar motivation.

The difference is that punishment and privation alternate with indulgence, or that self-punishment injects itself into the very experience of indulgence. It is common in these individuals to carry indul-

gence to excess until whatever element of pleasure the indulgence might promise is vitiated by the painful effects of the excess. This is clearly illustrated in those criminals who after committing a crime seem to leave no stone unturned and miss no opportunity for a slip-up, until they are detected and punished for the crime. But ultimately, the goal of life and activity in the impulsive as well as the reactive type is suffering and defeat. Now the human being has always been subject to the types of distorted management of his nature that we described above, certainly since the beginnings of civilization. He has always resorted to various measures for the relief of the discomforts and the inadequacies which failure to manage the intrapsychic conflict brought in its wake. To review even very briefly the history of man's effort to deal with the difficulties of his own nature and to bring it into accord with the requirements of reality would carry us considerably beyond the scope of this paper. It would involve a review of his experimentations with magic and religion and with the early gropings after a more disciplined psychological medicine. But whatever these methods might have been, whether suggestion, persuasion reeducation, or hypnosis, none could have as its objective anything beyond the removal of existing symptoms. Apart from the fact that they all ignored the unconscious sources of human motivation, their influence was limited to the conscious self, and with the exception of Freud's employment of hypnosis for effective-discharge purposes during the early stages of the psychoanalytic movement, they never reached unconscious sources of difficulty. The advent of psychoanalysis brought with it a radical shift of aim; the aim of therapy became the ridding of the individual of the need for symptom formation. A successfully completed psychoanalysis not only rids the patient of his symptoms, but brings about a degree of extension of conscious or ego control over unconscious impulse which eliminates the need for pathological methods for dealing with the internal conflict.

When Professor Freud was led, because of a deeper insight into the question of hypnosis than had been available up to that time, to an application of the technic of hypnosis to the release of pent-up systems of ideas of a high emotional value to the

patient—his so-called cathartic method—he did not foresee that a technic which was primarily intended as a therapeutic instrument would turn out to be the most reliable as well as the most revelatory technic of research into the nature of the human being.

Naturally, there is a reciprocal influence at work here. The wider therapeutic application has tended to deepen our knowledge concerning the nature of man, and the increase of knowledge has led in turn to an extension of the field of practical usefulness of psychoanalysis. One might, for instance, consider the beneficent possibilities of a general acceptance of the viewpoint that "normality," that is, the capacity for a healthy, adequate adjustment to the requirements of life in society, is not the natural birthright of man, but a dearly bought individual achievement in the face of tremendous obstacles. The successful evolution from the amoral and asocial state of infancy to a state of healthy maturity implies the adequate mastery of powerful tendencies of an opposite aim. Conversely, the various manifestations of difficulty or failure of adjustment to the requirements of civilized life reflect a yielding to a greater or less degree to the tendencies which oppose this process of growth and maturity.

Even in connection with the brief allusion to the nature of man as expressed above it is already possible to discern some of the underlying tenets of psychoanalytic theory. The concept "psychological" acquires a broadened and deepened meaning. It is not limited to phenomena of consciousness, but includes a wealth of significant psychological manifestations which belong to the life and activities of the unconscious, a region of the personality accessible to our vision only by special methods of approach, the methods of free association, and by hypnosis. Furthermore, psychological phenomena, in the psychoanalytic sense, are charged with a dynamic quality: they are energy carriers capable of affecting the feeling and striving and acting of the human being. Finally, psychoanalysis has demonstrated that not all psychological manifestations of the personality are subject to the laws of reason and logic. Only those psychological man-

ifestations which issue from the conscious self, the adjusted part of the personality, are subject to these laws. The manifestations of the unconscious, as, for instance, the rich and complex phenomena of the dream, do not heed any of the laws which govern the stream of consciousness.

A passing reference was made earlier in this presentation to the concept of the "Id," the primitive, instinctual reservoir which binds the individual to everything that has characterized the evolution of the human race. I shall not undertake at this point a detailed consideration of this important concept in the structure of psychoanalysis. But it should be obvious that the acceptance of this idea of a living and enduring past entering so largely into the shaping of the destiny of the individual must profoundly modify one's traditional notions concerning the characteristics of man. We have already indicated this when we stressed the idea that "normality," or "morality," or "social-mindedness"—in short, those various virtues which are cultivated and pursued in the service of man's need for adaptation to the demands of his social environment—cannot be considered as the natural heritage of man, but rather as a dearly bought achievement, a product of the adjustment of man's nature to the requirements of culture. Man's heritage is of an altogether different kind, and is primarily, if not exclusively, concerned with his needs as a biologic organism. In view of this it should not be difficult to find oneself in agreement with the psychoanalytic conception of the sexuality of man. Such a conception of the sexual or love life of man embraces not only its qualities of physiological craving and biological purpose, but also those of human value and idealized aim. It is in its very nature not limited to "genital functioning," but in its pregenital phases is antibiological and antisocial in nature, whereas in its sublimated phases it constitutes the source and inspiration of the most treasured values in the cultural heritage of man.

The practical significance of a general fertilization of contemporary culture by these few fundamental concepts of psychoanalytic theory can hardly be overstressed. It has already profoundly modified our thinking in many departments of life.

130 EAST 39TH ST.

DEPARTMENT OF HEALTH DIAGNOSTIC CARDIAC CLINIC OF NEW YORK CITY*

MORRIS GOODMAN, M.D., and JOSEPHINE W. PRESCOTT, M.A.

New York, N. Y.

INTRODUCTION.—The Department of Health Diagnostic Cardiac Clinic is a recent development in Health Department activities in New York City. Its main purpose is to determine the cardiac diagnosis and physical fitness for employment of children who apply for working papers and who are found to have some cardiac condition—a murmur, arrhythmia, or evidence of cardiac enlargement. It also endeavors to obtain medical supervision and vocational guidance, until the age of 17, for all children who have organic heart disease.

For the three years ending December, 1932, an average of 84,000 children between the ages of 14 and 17 have applied for working certificates yearly. At the time of their examination for working papers, about 1.3 per cent of these children were found to have cardiac abnormalities. The procedure has been to group these children into those with organic heart disease, who are either refused or granted limited working certificates, or into those with "functional abnormalities," all of whom are granted unlimited working certificates. This grouping, up to October, 1930, was made at the Department of Health Mercantile Office, where medical facilities, both as to the number of physicians and equipment for cardiac diagnoses, were inadequate.

The diagnostic cardiac clinic was created in the Fall of 1930 to overcome this difficulty and to reduce errors in diagnosis to a minimum. It is organized and equipped to examine 1,000 children a year. The equipment includes facilities for taking and developing teleroentgenograms and electrocardiograms.

AFFILIATED AGENCIES.—In establishing this clinic, it was found essential that interested organizations should assist in its organization, functioning, and support.

The clinic is operated by the Bureau of Child Hygiene of the Department of Health, in cooperation with the Heart Committee of the New York Tuberculosis

and Health Association and the Bellevue-Yorkville Health Demonstration.

A valuable service is given by the Employment Center for the Handicapped in supervising and in many cases obtaining suitable employment for the child with heart disease. The field nursing service of the Department of Health has rendered possible home visits to those children living in the five boroughs of Greater New York, while the Association of Volunteers and the Department of Education contribute workers to assist with the clinic procedure.

ORGANIZATION AND PERSONNEL.—The general plan of organization is illustrated in Chart I. The several agencies work through the medium of the Bellevue-Yorkville Health Center, where the clinic is housed. The chart shows the contribution of each agency. The squares with the broken lines (laboratory and employment service) indicate activities outside the clinic.

The personnel during the clinic sessions is made up of one physician, one nurse, three volunteers, a certificating officer from the Department of Education, and a part-time x-ray and electrocardiographic technician. The workers average about six hours a week in the clinic, with the exception of the nurse, who must spend an extra day a week on records, the doctor who spends only four hours a week, and the x-ray and electrocardiographic technician, who averages two and one-half days a week.

CLINIC EQUIPMENT.—It is important, in planning a cardiac clinic such as this, that sufficient space be provided so that the physician, the historian, and the conference nurse may all privately interview the patients.

This clinic is equipped with a waiting room to which the children are admitted, a private room for history taking, two dressing booths, two toilets with hand-washing facilities, an ante-room in which those who are ready may wait for the doctor, and an examining room.

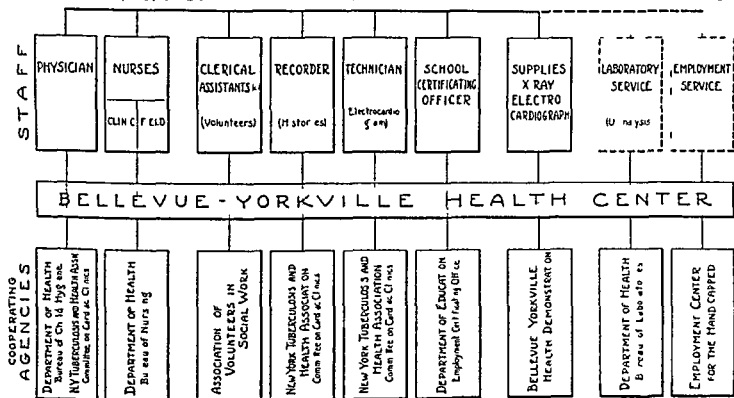

* In cooperation with the Board of Education, the Heart Committee of the New York Tuberculosis and Health Association, the Employment Center for the Handicapped, and the Bellevue-Yorkville Health Demonstration.

The supplies for the nurse's use consist of a desk, scales for height and weight, thermometer set up, bottles for urine specimens, and record forms. Outing flannel coats are provided for the children, who strip to the waist for examination.

The supplies for the doctor's use consist of a desk, a viewing box for the x-ray films, an examining table, a stethoscope, a blood pressure machine, and tongue depressors.

physicians or clinics for correction before qualifying them. Those who have any cardiac abnormality, organic or functional, are referred to the Department of Health Diagnostic Cardiac Clinic. Here they are divided into two groups, those who have organic heart disease and those with functional abnormalities. The latter are all granted unlimited working certificates. The children with organic heart disease and who are under 16 years of age are

(For Children Applying for Work Certificates) Bellevue Yorkville Health Center New York City

* Organized for examination of 1 000 children a year

† Ages 14-17 years

GENERAL PROCEDURE—The plan of procedure is illustrated in Chart II. When a child in New York City wishes to obtain working papers, he applies to the principal of the school he attends for a schooling record. The principal in turn refers him to a mercantile office of the Department of Health for a physical examination to determine his fitness. At the mercantile office, children of the proper age who have completed the required amount of schooling and are found to be in good physical condition, are granted unlimited working certificates*. Those with defects other than cardiac are referred to their private

refused certificates. Those over 16 who show good cardiac reserve are granted limited working certificates and are referred to the Employment Center for the Handicapped for work supervision. Those with poor reserve are refused certificates.

The clinic has been very desirous of winning the cooperation of the private physicians and clinic physicians and extending to them any help which it has to offer. For this reason a copy of the complete record including a strip of the electrocardiogram, a tracing of the tele-roentgenogram and recommendations are sent upon request to any private physician or clinic whose patient has been examined.

CLINIC PROCEDURE—Each child must report twice before a diagnosis is made. On the first visit, the child's history is obtained, an x-ray and electrocardiogram are taken, and a urine specimen is procured. His height and weight are re-

* See Section 635 Law in regard to the physical examination of applicants for employment certificates. Children may go to work in New York City provided they are 14 years of age and have completed 8B when they are 15 and have completed 6B or when they are 16 and have passed the physical requirements test regardless of school grade. When a minor from 16 to 17 years of age is not physically sound but in the opinion of the physician may safely engage in certain occupations he may be granted a certificate of limited physical fitness.

corded. Information for the Department of Education reports is obtained at this time. The child is then directed to return to the clinic at the next session.

On his second visit, the child's temperature, pulse, and respiration are taken. His history, x-ray, electrocardiogram, and urine reports are sent to the doctor. The child is then examined by the doctor, who dictates his findings and diagnosis to one of the volunteer workers.

Not infrequently in the course of the examination, abnormalities other than cardiac are observed. Among these are pathological urines, enlarged thyroids, and chest conditions. When this is the situation, the nurse refers the child to his private physician or to a clinic with instructions to bring a written statement as soon as the defects are corrected or under care. The working certificate is held up until this note is received.

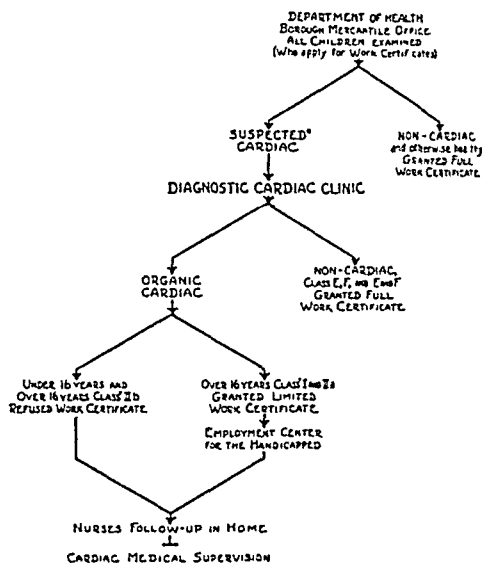

Those children who are eligible for limited certificates are referred to the Employment Center for the Handicapped for vocational guidance and approval of the positions which the children have been promised by employers. If the positions are not on the approved list for cardiac children, the Employment Center for the Handicapped sends an investigator to determine the suitability.

Everyone granted a limited certificate is required to report to the cardiac clinic for reexamination every six months until he is 17 or whenever he changes his work. If he is still considered by the doctor as eligible for a limited certificate, he is sent again to the Employment Center for the Handicapped.

THE PHYSICAL EXAMINATION.—The examination is made by a cardiologist. The physical record recommended by the Heart Committee of the New York Tuberculosis and Health Association is used. The following examinations are omitted: retinoscopy, sinus examination, percussion of cardiac dulness, and chest and abdominal measurements. The heart is examined in the upright and recumbent positions and also after exercise. The electrocardiogram and x-ray interpretations, as well as urine findings, are charted. No further tests are included. The complete cardiac diagnosis is recorded—etiological, anatomical, physiological, and functional. The latter is determined on the history of ability to climb stairs and on the impression of the

examining physician. No functional test is used. The organic diagnosis is based on the criteria set forth by the Heart Committee of the New York Tuberculosis and Health Association. The borderline case with a systolic murmur at the apex is examined fluoroscopically, and where indicated, the examinations are repeated.

CHART II.—DISPOSITION OF SUSPECTED* CARDIAC CHILDREN APPLYING FOR WORK CERTIFICATES

* All children, ages 14-17, with Cardiac Abnormality.

† Class E: Abnormal Signs and Symptoms.

Class F: Potential Cardiac (Rheumatic History).

Class I: Organic Cardiac-Functional Capacity Unimpaired.

Class 2a: Organic Cardiac-Functional Capacity Slightly Impaired.

Class 2b: Organic Cardiac-Functional Capacity Greatly Impaired.

THE DUTIES OF THE PERSONNEL.—The choice of a physician for the cardiac clinic was considered most important. As this clinic was a new development of the Department of Health, it was necessary to have a physician who could help organize the clinic in all its details. The physician not only makes all the examinations and determines when children are eligible for working papers, but continues to work closely with the Department of Health and co-operating agencies in the development of this clinic.

The selection of a supervising nurse is of equal importance, since she is directly responsible for helping with the organization of the clinic and ascertaining that the routines are properly carried out.

The clinic nurse is responsible for the general routines in the clinic and also for

interviews with both child and parent. It is of considerable importance in a diagnostic clinic which does not give medical supervision to impress on the parents the necessity of medical care for children with organic heart disease. For this purpose parents are sent instructions to be present when their children are examined. Each parent is interviewed by the conference nurse who not only advises about medical supervision but also concerning any social or economic problems. Only those families are visited who neglect to obtain medical care for their children, or where there are special social or economic difficulties. Information concerning medical supervision is confirmed by form letters sent to the private physicians or clinics with whom the children are reported registered, or by telephone calls when the letters are not answered.
